The baculovirus *Autographa californica* multiple nucleopolyhedrovirus (AcMNPV) can infect a variety of mammalian cells, as well as insect cells, facilitating its use as a viral vector for gene delivery into mammalian cells. Glycoprotein gp64, a major component of the budded AcMNPV envelope, is involved in viral entry into cells by receptor-mediated endocytosis and subsequent membrane fusion. We examined the potential production of pseudotype baculovirus particles transiently carrying ligands of interest in place of gp64 as a method of ligand-directed gene delivery into target cells. During amplification of a gp64-null pseudotype baculovirus carrying a green fluorescent protein gene in gp64-expressing insect cells, however, we observed the high-frequency appearance of a replication-competent virus incorporating the gp64 gene into the viral genome. To avoid generation of replication-competent revertants, we prepared pseudotype baculoviruses by transfection with recombinant bacmids without further amplification in the gp64-expressing cells. We constructed gp64-null recombinant bacmids carrying cDNAs encoding either vesicular stomatitis virus G protein (VSVG) or measles virus receptors (CD46 or SLAM). The VSVG pseudotype baculovirus efficiently transduced a reporter gene into a variety of mammalian cell lines, while CD46 and SLAM pseudotype baculoviruses allowed ligand-receptor-directed reporter gene transduction into target cells expressing measles virus envelope glycoproteins. Gene transduction mediated by the pseudotype baculoviruses could be inhibited by pretreatment with specific antibodies. These results indicate the possible application of pseudotype baculoviruses in ligand-directed gene delivery into target cells.

The baculovirus *Autographa californica* multiple nucleopolyhedrovirus (AcMNPV) is an insect virus possessing a 134-kb double-stranded circular DNA genome (3). Due to the strong polyhedrin and p10 promoters, baculovirus is commonly used as a tool for the large-scale production of recombinant protein in insect cells (32, 38). Baculovirus is also capable of entering into a variety of mammalian cells to facilitate the expression of foreign genes under the control of the mammalian promoters without replication of the viral genome (8, 21, 61). Therefore, baculovirus is a useful viral vector, not only for the abundant expression of foreign genes in insect cells, but also for efficient gene delivery to mammalian cells (29). AcMNPV has a number of unique beneficial properties as a viral vector, including a large capacity for foreign gene incorporation, easy manipulation, and replication competence in insect cells combined with incompetence in mammalian cells. Therefore, the possibility of generating replication-competent revertants expressing baculoviral gene products, which can often lead to harmful immune responses against mammalian cells, is significantly lower than for other viral vectors presently in use. Furthermore, studies of host responses to baculovirus infection in vivo revealed that AcMNPV can stimulate interferon production in mammalian cell lines, conferring protection from lethal encephalomyocarditis virus infections in mice (18). Intranasal inoculation with AcMNPV also induces a strong innate immune response, protecting mice from lethal challenges of influenza A or B virus (1). The precise mechanism of protective immune response induction by AcMNPV, however, remains unclear.

Recently, several groups have reported enhanced gene transfer in a variety of cell lines infected with recombinant baculoviruses expressing either foreign viral envelope proteins, such as vesicular stomatitis virus envelope G protein (VSVG), or excess amounts of the endogenous envelope glycoprotein, gp64, on the virion surface (4, 65, 66). Although modification of the virion surface enhances the efficiency of gene transduction into a variety of cell lines, the utility of recombinant baculoviruses in cell-type-specific gene transduction is still unsatisfactory. Ojala et al. demonstrated that, while baculoviruses bearing either a single chain antibody fragment specific for carcinoembryonic antigen or a synthetic immunoglobulin G (IgG) binding domain derived from protein A could specifically bind target cells, cell type-specific gene transduction was unsuccessful (44, 45). Although gp64-null pseudotype baculoviruses expressing a foreign viral envelope protein, such as VSVG or fusion envelope glycoproteins from other baculoviruses, exhibited high infectivity to insect cells, their capacity for gene transduction into mammalian cells has yet to be explored (33, 34). The inefficiency of present gene transfer vectors in gaining entry into cells needing treatment can be problematic, as many therapeutic genes may be deleterious if delivered to bystander cells. Therefore, the development of a ligand-directed gene delivery vector capable of distinguishing between

† This study is dedicated to the memory of Ikuko Yanase

target and nontarget tissue is essential for both the safety and efficacy of gene therapy.

In this study, we examined the stability of a generated gp64-null pseudotype baculovirus possessing the green fluorescent protein (GFP) gene during passages in insect cells stably expressing the gp64 protein. Replication-competent revertant viruses emerged with high frequency during passage in the cell line, incorporating the gp64 gene into the revertants' viral genomes. To overcome the emergence of revertant viruses during passage, we generated recombinant bacmids lacking the gp64 gene and carrying a ligand of interest and a reporter gene under the control of the polyhedrin and the CAG promoters, respectively. Pseudotype baculoviruses generated from these bacmids exhibited specific ligand-directed gene delivery into target cells. These pseudotype baculovirus vectors may be useful in future clinical gene targeting.

MATERIALS AND METHODS

Cells. *Spodoptera frugiperda* (Sf9) cells were grown in TC-100 medium (Sigma, St. Louis, Mo.) supplemented with 0.26% tryptose phosphate broth (Difco, Detroit, Mich.) and 10% (vol/vol) fetal bovine serum (FBS) (Sigma) (66). To establish a cell line constitutively expressing gp64, Sf9 cells were transfected with pAFgp64 (see below) and pIB/V5-His (Invitrogen, Carlsbad, Calif.) using UniFector reagent (B-Bridge, Sunnyvale, Calif.). Thirty-six hours after transfection, Sf9 cells were selected in TC-100 medium containing blasticidin (50 μg/ml; Invitrogen). Resistant cells were stained with anti-gp64 antibodies (AcV1) (kindly provided by P. Faulkner) (22); positive cells were sorted using a FACSCalibur (Becton Dickinson, Franklin Lakes, N.J.) to establish a cell line, Sfgp64, stably expressing gp64 at the cell surface. The human embryonic kidney cell line 293T and the hamster kidney cell line BHK, purchased from the American Type Culture Collection, were maintained in Dulbecco's modified Eagle's medium (Sigma) containing 2 mM L-glutamine, penicillin (50 IU/ml), streptomycin (50 μg/ml), and 10% FBS (66).

Construction of plasmids. We constructed two expression plasmids, pAF-MCS1 and pAF-MCS2, harboring the A3 actin promoter, a multiple cloning site, and the polyadenylation signal derived from the *Bombyx mori* fibroin H-chain gene, for the subcloning of ligand molecules. First, the promoter and polyadenylation signal were excised from pA3Fb-Luc, kindly provided by H. Bando (Hokkaido University, Sapporo, Japan), and inserted into pUC18. To generate pAFgp64, the gp64 gene was excised from pFBgp64 (see below) by digestion with SalI and HindIII. This fragment was then inserted into the SalI-HindIII site of pAF-MCS1. Recombinant baculoviruses were constructed using the transfer vector pFASTBAC1 (Invitrogen). To measure the expression of foreign genes in mammalian cells, the firefly luciferase gene under the control of the CAG promoter (43) was subcloned into pFASTBAC1. To construct the transfer vector pFB-CAluc, the CAG-luciferase cassette was excised from pCAGluc (61) by digestion with SalI, extension with Klenow enzyme, and redigestion with BamHI and inserted into the SnaBI-BamHI site of pFASTBAC1.

pUCgp64locus was generated by cloning the EcoRI-SmaI fragment from AcMNPV genomic DNA (corresponding to 107,325 to 112,041 nt) (3) into the EcoRI-SmaI site of pUC18. To generate pUCgp64, a fragment encoding the gp64 gene was excised from pUCgp64locus by digestion with SpeI and BglII and then cloned into the XbaI-BamHI site of pUC18. The gp64 gene was excised from pUCgp64 by digestion with SalI and KpnI and inserted into the SalI-KpnI site of pFASTBAC1. The resulting plasmid was designated pFBgp64. To generate pFBgp64CAluc, the cassette including the polyhedrin promoter and the gp64 gene was excised from pFBgp64 by digestion with SnaBI and KpnI and cloned into pFBCAluc, which was digested with SalI, extended with Klenow enzyme, and redigested with KpnI. The VSVG gene fragment was excised from pCAG-VSVG (64) by digestion with EcoRI and cloned into the EcoRI site of pFASTBAC1 to create pFBVSVG. pFBGFP was constructed by excision of the GFP gene from pAcVSVG-CAGFP (65) by digestion with EcoRI and subsequent insertion into the EcoRI site of pFASTBAC1. To generate pFBVSVGCAluc and pFBGFPCAluc, the DNA fragment encoding the polyhedrin promoter and either the VSVG or GFP gene was excised from pFBVSVG or pFBGFP, respectively, by digestion with SnaBI and XhoI and cloned into pFBCAluc, which was digested with SalI, extended with Klenow enzyme, and redigested with XhoI.

cDNAs encoding human CD46 and signaling lymphocyte activation molecule (SLAM; also known as CDw150) were amplified from the genomic DNAs of CHO/CD46 (kindly provided by T. Seya) (25) and CHO.SLAM (kindly provided by Y. Yanagi) (67) cells, respectively, by PCR. The CD46-Fw (1st) (5′-TTT CCTCCGGAGAAATAACAGC-3′) and CD46-Rv (1st) (5′-CTAAGCCAC AGTTGCACTCATG-3′) primers were used to amplify CD46 cDNA, and the SLAM-Fw (1st) (5′-TGACACGAAGCTTGCTTCTG-3′) and SLAM-Rv (1st) (5′-GTCGACCTTTGTTGGTCTCTGGTG-3′) primers were used to amplify SLAM cDNA. These PCR products were used as templates for a second PCR with the primers CD46-Fw-*Hind*III (5′-CCCCAAGCTTCCGCGCCGCG CATGGG-3′) and CD46-Rv-*Sal*I (5′-TTTTGTCGACTCAGCCTCTCTGCTC TGCTG-3′) to amplify CD46 cDNA and SLAM-Fw-*Hind*III (5′-CCCCAAGC TTCCTCATTGGCTGATGGATC-3′) and SLAM-Rv-*Sal*I (5′-AAAAGTCGA CTCAGCTCTCTGGAAGTGTCA-3′) to amplify SLAM cDNA. The amplified CD46 and SLAM cDNAs were digested with HindIII and SalI and then cloned into the HindIII-SalI sites of pAF-MCS2 to create pAFCD46 and pAFSLAM, respectively. The CD46 and SLAM cDNAs were excised from pAFCD46 and pAFSLAM, respectively, by digestion with HindIII, extension with Klenow enzyme, and redigestion with XbaI and cloned into pFASTBAC1. To generate pFBCD46CAluc and pFBSLAMCAluc, the DNA fragments encoding the polyhedrin promoter and either the CD46 gene or the SLAM gene were excised from pFBCD46 or pFBSLAM, respectively, by digestion with SnaBI and PvuI and cloned into pFBCAluc. A mutant SLAM gene, SLAMcyto7, possessing a truncated cytoplasmic domain of 7 amino acids, was generated by PCR with the primers SLAM-Fw-SmaI (5′-CCCCCCGGGCCTCATTGGCTGATGGATC-3′) and SLAM-7aa-stop-Rv-*Sal*I (5′-GGGGGGTCGACTCAGTTCGTTTT ACCTCTTCTTCTCAAC-3′). This PCR product was digested with SmaI and SalI and then cloned into the SmaI-SalI sites of pAF-MCS1 to create pAFSLAMcyto7. To construct pFBSLAMcyto7CAluc, the SLAMcyto7 gene was excised from pAFSLAMcyto7 and substituted for the full-length SLAM gene of pFBSLAMCAluc. All plasmids containing PCR-derived sequences were confirmed by sequence analyses. For infection with pseudotype baculoviruses bearing CD46 or SLAM, we transfected target cells with expression plasmids encoding either the hemagglutinin and fusion proteins of the Edmonston strain (EdH and EdF) or those of the Ichinose strain (IcH and IcF) measles viruses. The pCA-EdH, pCA-EdF, pCA-IcH, and pCA-IcF plasmids were kindly provided by K. Takeuchi (63).

Construction of pseudotype baculoviruses. The gp64 gene of the AcMNPV-bacmid (bMON14272; Invitrogen) was replaced with the chloramphenicol acetyltransferase (CAT) gene as described previously with slight modifications (5, 33). Briefly, the CAT gene was amplified by PCR with the Chl-Fw-*Spe*I (5′-GGAC TAGTCCGAATAAATACCTGTGACGG-3′) and Chl-Rv-*Bgl*II (5′-GAAG ATCTCGTCAATTATTACCTCCACGG-3′) primers using the pBT plasmid (Stratagene, La Jolla, Calif.) as a template. Following digestion with SpeI and BglII, the amplified CAT gene replaced the gp64 gene of pUCgp64locus to create p64locus/cat. To construct a gp64-null AcMNPV-bacmid, bMONΔ64/cat, the p64locus/cat plasmid was linearized by digestion with NdeI and cotransfected with bMON14272 into Sf9 cells. Forty-eight hours posttransfection, the cells were washed with cold phosphate-buffered saline and lysed in proteinase K buffer (50 mM Tris-HCl [pH 7.4], 100 mM NaCl, 1 mM EDTA, and 0.5% sodium dodecyl sulfate [SDS]). DNA was purified from cell lysates by phenol-chloroform extraction and then transformed into *Escherichia coli* DH10B competent cells (Invitrogen) by electroporation using a Gene Pulser (Bio-Rad, Hercules, Calif.). Resistant colonies were selected in kanamycin and chloramphenicol. Disruption of the gp64 gene was confirmed by PCR in a bMON14272-transformed colony that was resistant to kanamycin and chloramphenicol (Fig. 1A). To generate DH10BacΔ64/cat, we cotransfected bMONΔ64/cat and the helper plasmid pMON7124 into DH10B cells. To construct recombinant bacmids, DH10BacΔ64/cat was transformed with transfer vectors and selected according to the manufacturer's instructions. To separate recombinant bacmids from the pMON7124 helper plasmid, miniprep bacmid DNA was transformed into DH10B cells by electroporation. To generate pseudotype baculoviruses, bacmids lacking the gp64 gene and possessing both an exogenous ligand gene and the luciferase gene under the polyhedrin and CAG promoters, respectively, were transfected into Sf9 cells. Fifteen micrograms of the bacmid DNA was used to transfect 5×10^6 Sf9 cells in a 10-cm-diameter dish by using 30 μl of UniFector reagent (B-Bridge). Four days after transfection, 500 ml of culture supernatants (50 dishes) was harvested. The resulting pseudotype baculoviruses, AcΔ64/gp64/CAluc, AcΔ64/VSVG/CAluc, AcΔ64/CD46/CAluc, AcΔ64/SLAM/CAluc, and AcΔ64/SLAMcyto7/CAluc, were concentrated ~2,000 times by ultracentrifugation as described previously (66). The number of virus particles was determined from the signal intensity by Western blotting for the capsid protein vp39. Although both AcΔ64/gp64/CAluc and AcΔ64/VSVG/CAluc infected and repli-

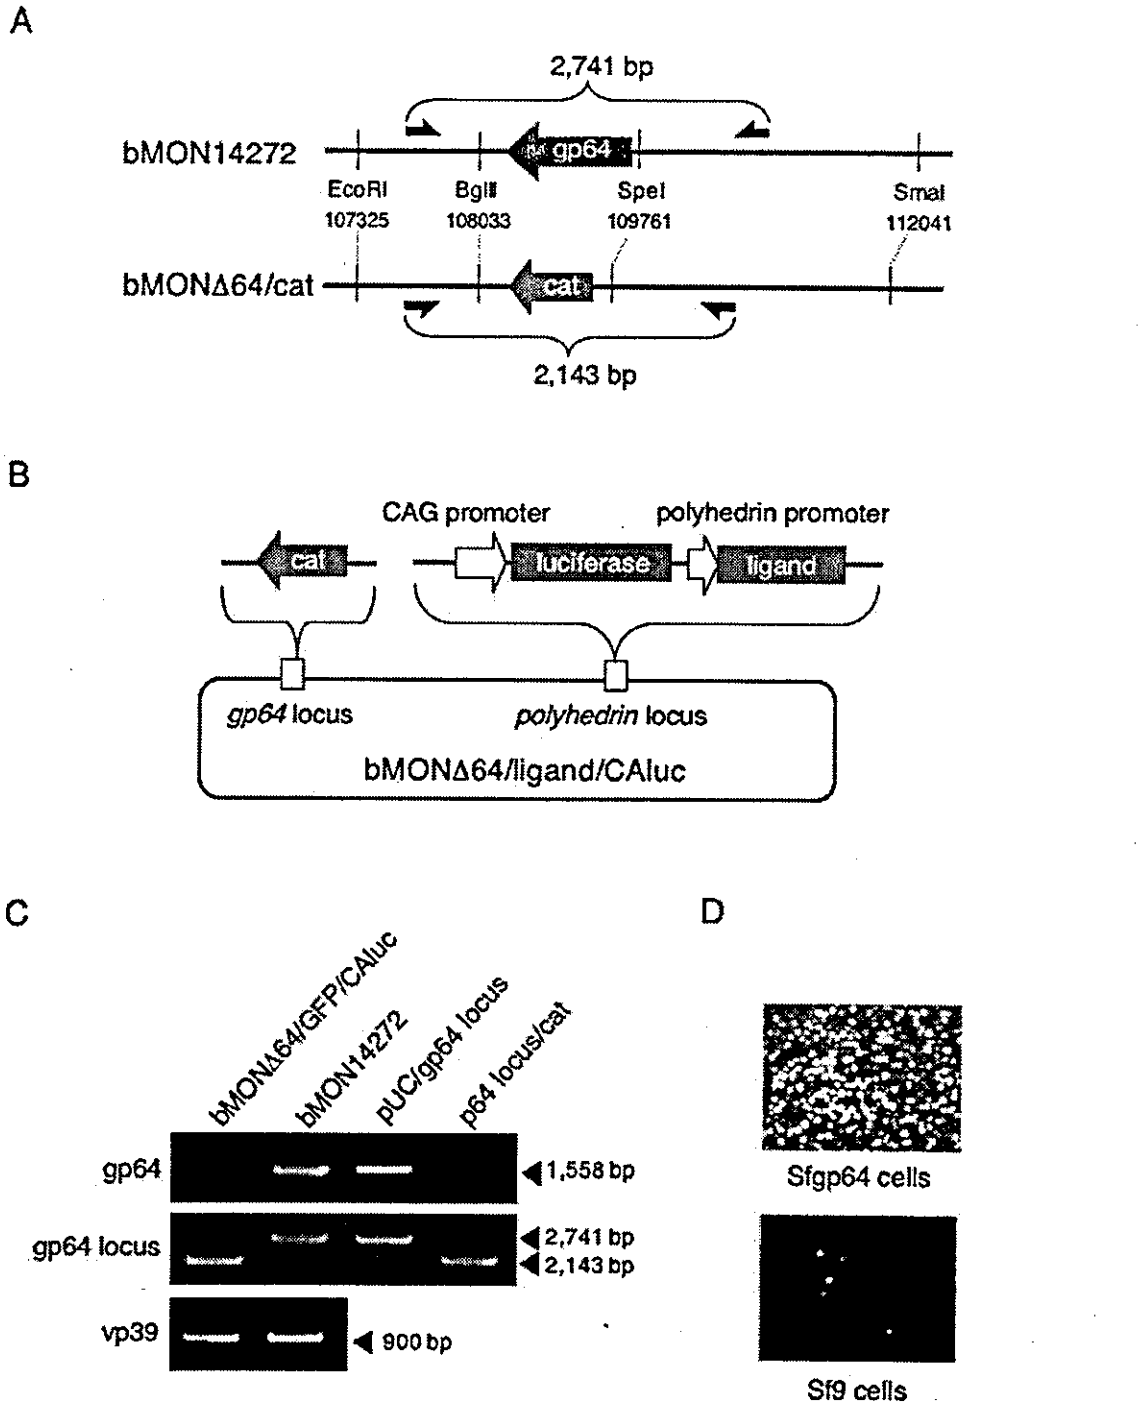

FIG. 1. (A) Schematic representations of the gp64 loci of the AcMNPV (bMON14272) and gp64-null AcMNPV (bMONΔ64/cat) bacmids. The gp64 gene (BglII/SpeI fragment corresponding to 108,033 to 109,761 nt) (3) of bMON14272 was replaced with the CAT gene by homologous recombination. The arrows indicate the locations of the PCR primers within the gp64 loci. (B) Construction of the recombinant bacmid bMONΔ64/ligand/CAluc. The gp64 gene in bMON14272 was replaced with the CAT gene. The desired ligand and luciferase genes were inserted under the control of the polyhedrin and CAG promoters, respectively, within the polyhedrin locus. (C) The bacmids bMONΔ64/ligand/CAluc and bMON14272 and plasmids containing the gp64 locus, pUC/gp64locus, and p64locus/cat (the gp64 locus with the CAT gene replacement) were amplified by PCR using primers specific for gp64, the gp64 locus, and vp39, a nucleocapsid protein of AcMNPV used as an internal control. Primers for gp64 and vp39 amplified fragments of 1,558 and 900 bp, respectively. The gp64 locus primers generated 2,741- and 2,143-bp fragments corresponding to the wild-type gp64 locus and the mutant locus with the CAT gene replacement shown in panel A, respectively. (D) Sfgp64 and Sf9 cells were transfected with bMONΔ64/GFP/CAluc. GFP expression was examined by fluorescence microscopy 4 days posttransfection.

cated in Sf9 cells, it was not possible to determine the infectivity in the cases of the pseudotype baculoviruses possessing ligands incapable of entering into insect cells. To standardize the viral titer, we determined the amount of viral capsid protein vp39 by semiquantitative Western blot analysis. The infectious titer determined by plaque assay in Sf9 cells correlated well with the intensity of the vp39 signal obtained by Western blotting for both AcΔ64/gp64/CAluc and AcΔ64/VSVG/CAluc (data not shown). Pseudotype baculovirus titers are expressed as relative infectious units (RIU) in this study. To confirm the absence of gp64 in the bacmids, we synthesized oligonucleotide primers specific for the gp64 gene, the gp64 locus, and the vp39 gene as follows: for the gp64 gene, gp64-Fw (Bgl) (5'-AAAGATCTACCATGGTAAGCGCTATTGTTT-3') and gp64-Rv (Sal) (5'-TTGTCGACTTAATATTGTCTATTACGGTTT-3'); for the gp64locus, gp64locus-Fw (5'-GCACGGATTGGGGAGAGGACGGATTTT-3') and gp64locus-Rv (5'-AGCTCGTTATTCAAGTGTCCCGCGTAC-3'); and for vp39, vp39-Fw (5'-ATATGGCGCTAGTGCCCGTGGGTATGG-3') and vp39-Rv (5'-GACGGCTATTCCTCCACCTGCTGCCTG-3'). PCR amplification was performed using *Taq* DNA polymerase (Invitrogen) according to the manufacturer's protocol.

Stability of pseudotype baculoviruses during passage in Sfgp64 cells. Culture supernatants from Sfgp64 cells transfected with recombinant bacmids were harvested 4 days after transfection. After serial passage in Sfgp64 cells for 4 days, each Sfgp64 cell supernatant was inoculated into Sf9 cells. The culture supernatants were further inoculated into Sf9 cells to examine the generation of replication-competent revertants during the replication in Sfgp64 cells. The presence of replication-competent virus in the culture supernatants was assessed by the appearance of cytopathic effect and GFP expression in Sf9 cells. GFP expression in insect cells was observed by fluorescence microscopy (UFX-II; Nikon, Tokyo, Japan). The generation of replication-competent viruses incorporating gp64 was examined by PCR using the viral DNA as a template. The supernatants of Sfgp64 cells were concentrated by centrifugation at 18,000 × *g* for 45 min at 4°C. Viral DNA, purified from replication-competent revertants by phenol-chloroform extraction, was examined by Southern blot analysis. DNA was digested with BglII or PstI, separated by electrophoresis on a 0.6% agarose gel, and transferred to a Hybond N+ nylon membrane (Amersham Biosciences, Piscataway, N.J.). PCR primers [gp64-Fw (Bgl) and gp64-Rv (Sal) for the gp64 gene or vp39-Fw and vp39-Rv for the vp39 gene] were used to amplify the target fragments for use as hybridization probes. PCR products were purified and labeled using the ECL direct nucleic acid labeling and detection system (Amersham Biosciences) according to the manufacturer's instructions. Fragments containing the gp64 or vp39 gene were visualized using image analyzer LAS-3000 (Fujifilm, Tokyo, Japan).

Incorporation of ligands into pseudotype particles. To examine the expression of ligand proteins in insect cells or the incorporation of the ligands into pseudotype particles, cell lysates or purified baculoviruses were separated by SDS-polyacrylamide gel electrophoresis and electroblotted onto Hybond-P polyvinylidene difluoride membranes (Amersham Bioscience). After being blocked in phosphate-buffered saline containing 5% skim milk and 0.05% Tween 20 (Sigma), the membranes were incubated at room temperature for 1 h with a rabbit polyclonal anti-CD46 antibody (H-294; 1:200) (Santa Cruz, Santa Cruz, Calif.) or one of the following mouse monoclonal antibodies: anti-gp64 (AcV5; 1:1,000) (kindly provided by P. Faulkner) (22), anti-VSVG (P5D4; 1:2,000) (Sigma), anti-SLAM (123317; 1:200) (R&D systems, Minneapolis, Minn.), or anti-vp39 (236; 1:2,000) (kindly provided by G. F. Rohrmann) (51). The membranes were then incubated in horseradish peroxidase-conjugated anti-mouse IgG or anti-rabbit IgG antibodies at room temperature for 1 h. Immunoreactive bands were visualized using enhanced-chemiluminescence Super Signal West Femto substrate (Pierce, Rockford, Ill.) (47).

Reporter gene expression by pseudotype baculoviruses. AcΔ64/gp64/CAluc and AcΔ64/VSVG/CAluc baculoviruses were inoculated into 3.0×10^4 293T and BHK cells. Twenty-four hours after infection, the cells were lysed in Bright-Glo luciferase substrate (Promega, Madison, Wis.) according to the manufacturer's instructions. Relative light units were measured using a luminometer (AB-2200; ATTO Co. Ltd., Tokyo, Japan). To demonstrate ligand-directed gene targeting by AcΔ64/CD46/CAluc, AcΔ64/SLAMCAluc, and AcΔ64/SLAMcyto7/CAluc baculoviruses, 3.0×10^4 BHK cells were cotransfected with either pCA-EdF and pCA-EdH or pCA-IcF and pCA-IcH and then infected with 5.0×10^6 RIU of pseudotype baculoviruses at 24 h posttransfection. Luciferase expression was determined after a 24-h incubation.

Inhibition of gene transduction by specific antibodies against ligands. To examine ligand-directed gene transduction by pseudotype baculoviruses, we examined the neutralization of gene transduction by antibodies specific for the ligands presented by the pseudotypes. The appropriate dilutions of anti-gp64 (AcV1), anti-VSVG (I1) (kindly provided by M. A. Whitt) (30), anti-CD46 (M75) (Seikagaku Co. Ltd., Tokyo, Japan), or anti-SLAM (IPO-3) (Biodesign International, Saco, Maine) antibodies were preincubated with each virus (10^6 RIU) at 37°C for 60 min and then inoculated into the appropriate target cells. After incubation at 37°C for 24 h, we determined the neutralization by the included antibodies from the reduction of luciferase expression.

Entry of pseudotype baculovirus into target cells. BHK cells expressing hemagglutinin and fusion proteins derived from the Edmonston strain of measles virus were preincubated with either ammonium chloride (2, 10, or 50 mM) (Wako Pure Chemical Industries, Osaka, Japan) or chloroquine (20, 100, or 500 μM) (Sigma) for 1 h. The cells were then inoculated with 1.0×10^6 RIU of AcΔ64/CD46/CAluc, AcΔ64/gp64/CAluc, or AcΔ64/VSVG/CAluc in the presence of the above-mentioned reagents. The effects of ammonium choloride and chloroquine on gene transduction by pseudotype baculoviruses were determined by the changes in luciferase expression.

Electron microscopy. Viral particles purified by ultracentrifugation as described above were put onto carbon-coated copper 400-mesh electron microscopy grids for 15 min. After being washed in water, the grids were negatively stained with 1% (wt/vol) uranyl acetate and examined using a Hitachi (Tokyo, Japan) H-7100 electron microscope at 75 kV. For immunoelectron microscopy, virus particles put onto grids were incubated with murine monoclonal antibodies specific for VSVG (I1) or CD46 (E4.3) (Santa Cruz) and then treated with a gold particle-conjugated anti-mouse IgG antibody (British Biocell International, Ltd., Cardiff, United Kingdom). Samples were stained and observed as described above.

RESULTS

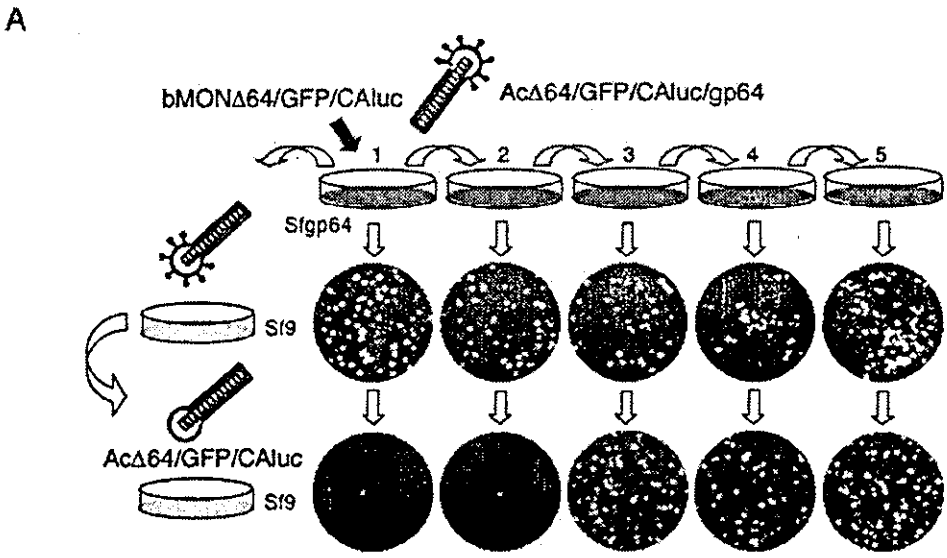
Construction of recombinant AcMNPV lacking the gp64 gene. The gp64 gene of the AcMNPV bacmid, bMON14272, was replaced with the CAT gene by homologous recombination in Sf9 cells using a modification of the methods reported by Bideshi and Federici (5) and Lung et al. (33) (Fig. 1A). We cotransfected bMON14272 and a linearized p64locus/cat plasmid bearing the CAT gene in place of the gp64 gene into Sf9 cells. DNA, extracted from the cells 48 h after transfection, was then transformed into competent DH10B cells. The disruption of the gp64 gene in colonies selected with kanamycin and chloramphenicol was confirmed by PCR (data not shown). We also constructed a recombinant bacmid, bMONΔ64/GFP/CAluc, which contained the insertion of the GFP gene under the control of the polyhedrin promoter and the luciferase gene under the control of the CAG promoter into the polyhedrin locus of the gp64-null bacmid (Fig. 1B). Disruption of gp64 in bMONΔ64/GFP/CAluc was confirmed by PCR using a series of specific primers (Fig. 1C). PCR with primers specific for the vp39 gene, used as an internal control for the AcMNPV bacmid, amplified a 900-bp product from both the bMONΔ64/GFP/CAluc and parent bMON14272 bacmids. The gp64 gene (1,558 bp) was amplified from bMON14272 and pUC/64locus, but not from bMONΔ64/GFP/CAluc and p64locus/cat. The 2,741- and 2,143-bp fragments corresponding to the wild-type and mutant gp64 genes, respectively, were amplified using gp64 locus-specific primers. The wild-type gene was amplified from bMON14272 and pUC/gp64locus, while the mutant gene was amplified from bMONΔ64/GFP/CAluc and p64locus/cat (Fig. 1A and C). These data indicate that the gp64 gene was replaced with the cat gene in bMONΔ64/GFP/CAluc. Previous studies demonstrated that gp64-null AcMNPV could propagate in $Sf9^{OP64\text{-}6}$ or $Sf9^{Op1D}$ cell lines constitutively expressing the gp64 protein of *Orgyia pseudotsugata* NPV (OpNPV) but not in untransfected Sf9 cells (40, 49). We then established a cell line, Sfgp64, constitutively expressing the gp64 gene derived from AcMNPV. The pAFgp64 plasmid, carrying the gp64 gene of AcMNPV without any flanking sequence, was used to

avoid homologous recombination between the viral genome and the plasmid. To examine the replication competency of gp64-null AcMNPV (AcΔ64/GFP/CAluc), Sfgp64 and Sf9 cells were transfected with bMONΔ64/GFP/CAluc. We assessed the propagation of infectious virus by measuring GFP expression by fluorescence microscopy. Forty-eight hours posttransfection, ~10% of the Sfgp64 and Sf9 cells were GFP positive (data not shown). While Sfgp64 cells exhibited the spread of infection 96 h posttransfection, Sf9 cells did not (Fig. 1D). These data indicate that AcΔ64/GFP/CAluc can replicate only in Sfgp64 cells, not in Sf9 cells.

Appearance of revertants incorporating the gp64 gene during replication in Sfgp64 cells. To determine the stability of AcΔ64/GFP/CAluc during replication in Sfgp64 cells, we serially passaged AcΔ64/GFP/CAluc in Sfgp64 cells. Culture supernatants of Sfgp64 cells collected 4 days after transfection with bMONΔ64/GFP/CAluc (passage 1) were inoculated into Sfgp64 cells. The supernatants were further passaged in Sfgp64 cells for 4 days. To examine the appearance of replication-competent viruses, the culture supernatants from each passage were inoculated into Sf9 cells. At 4 days postinfection, we examined GFP expression in Sf9 cells by fluorescence microscopy (Fig. 2A). The expression of GFP was observed in Sf9 cells inoculated with Sfgp64 culture supernatants, irrespective of the passage history. As gp64-negative AcΔ64/GFP/CAluc baculovirus only transiently carries gp64, progeny viruses produced in Sf9 cells should not be infectious. The supernatants of Sf9 cells inoculated with supernatants recovered after >3 passages (passages 3, 4, and 5) with Sfgp64 cells exhibited infectivity to Sf9 cells, suggesting the generation of replication-competent revertants incorporating the gp64 gene into the viral genome. To confirm the incorporation of gp64 into the viral genome, virus particles were purified from the supernatants of each Sfgp64 passage. The presence of the gp64 gene within the viral genome was determined by PCR. We detected the gp64 gene in viruses obtained from the culture supernatants of passages 3, 4, and 5 but not in those from the first and second passages (Fig. 2B). Furthermore, PCR amplification of viral DNA with the gp64 locus-specific primers revealed that a 2,143-bp fragment, corresponding to the mutant form, was detected in the genome of AcΔ64/GFP/CAluc, while a 2,741-bp fragment, corresponding to the wild-type form, was amplified from Ac14272, irrespective of the number of passages. These results confirmed that the emergence of replication-competent virus during the passage in Sfgp64 cells is not due to the contamination of the parental virus, Ac14272. The recombinant virus incorporated the gp64 gene into the AcΔ64/GFP/CAluc genome during propagation in Sfgp64 cells.

Plasmid DNA can be integrated into multiple sites within the viral genome by nonhomologous recombination upon cotransfection of plasmid DNA with the baculovirus genome in Sf9 cells (71). To determine if gp64 genes integrated into the baculovirus genome by nonhomologous recombination during propagation in Sfgp64 cells, we analyzed the DNAs of three independent revertant viruses by PCR and Southern blot analyses. Viral DNA was extracted from these revertant viruses and analyzed by PCR as described above (Fig. 3A). We detected the gp64 gene in all revertant viruses and bMON14272 but not in the parental bacmid, bMONΔ64/GFP/CAluc. The gp64 locus primers amplified the mutant 2,143-bp fragment from all revertant viruses and the parental bMONΔ64/GFP/CAluc bacmid, not the 2,741-bp wild-type fragment that could be amplified from bMON14272. These results confirmed that the three independent revertant viruses, instead of deriving from contaminating wild-type virus, had incorporated the gp64 gene into their genomes exogenously. DNA from the revertants was digested with BglII or PstI, which do not digest sequences within the gp64 or vp39 genes, and hybridized to gp64- or vp39-specific probes (Fig. 3B). If the gp64 gene integrated into the viral genome by nonhomologous recombination, the digested fragments containing the gp64 gene would be of different sizes. Following digestion with BglII, the DNA fragments containing the gp64 gene in the revertants differed in size from each other (Fig. 3B, lanes 3 to 5). When digested with PstI, the sizes of the fragments containing the gp64 gene were similar in revertant clones 2 and 3 (Fig. 3B, lanes 9 to 10), indicating that the gp64 gene may have integrated into nearby sites in the viral genomes of clones 2 and 3. The fragment containing the gp64 gene in revertant clone 1 following digestion with either BglII or PstI was similar to that seen in bMON14272 (Fig. 3B lanes 3 and 8). These results, however, were not due to contamination with bMON14272, as the PCR analysis demonstrated that the gp64 locus of revertant clone 1 was of the mutant type (Fig. 3A). These data suggested that the gp64 gene integrated into the virus genomes of the revertants by nonhomologous recombination. As an internal control, the vp39 gene was detected in fragments of the predicted sizes (31,975 bp when digested with BglII and 29,009 bp when digested with PstI) in all viruses. To determine the sites of integration of the gp64 gene in the genomes of the revertants, we tried to sequence from within the gp64 gene out into the baculovirus genome by using an internal gp64 primer. In revertant 2, the sequences including the actin promoter and the gp64 gene were detected upstream of the polyhedrin promoter, where no homologous sequence was observed. In revertants 1 and 3, however, sequence analyses by the internal primer obtained only sequences of pAFgp64 and could not reach the integration site, due to a large insertion of the plasmid sequence (data not shown).

Characterization of pseudotype baculovirus carrying VSVG. Previous studies demonstrated that the gp64 protein plays a critical role in infection of various mammalian cells, as well as insect cells (66). To determine if the pseudotype baculoviruses bearing foreign viral envelope proteins in place of gp64 can infect and express foreign genes within mammalian cells, we constructed a gp64-null pseudotype virus, AcΔ64/VSVG/CAluc, by the transfection of bMONΔ64/VSVG/CAluc, which encodes the VSVG gene under the control of the polyhedrin promoter and the luciferase gene under the control of the CAG promoter, into Sf9 cells (Fig. 1B). As a control, we also generated AcΔ64/gp64/CAluc, in which the gp64 gene under the control of the polyhedrin promoter replaced the VSVG gene in the above-mentioned virus. Sf9 cells were transfected with appropriate bacmids and incubated for 4 days. The pseudotype baculoviruses in the culture supernatants were concentrated and purified by ultracentrifugation (10^8 to 10^9 RIU/ml). To examine the expression and incorporation of the glycoproteins into virions, we transfected these bacmid constructs into Sf9 cells. The cell lysates and the purified virus particles were examined by Western blot analysis (Fig. 4A). VSVG and gp64



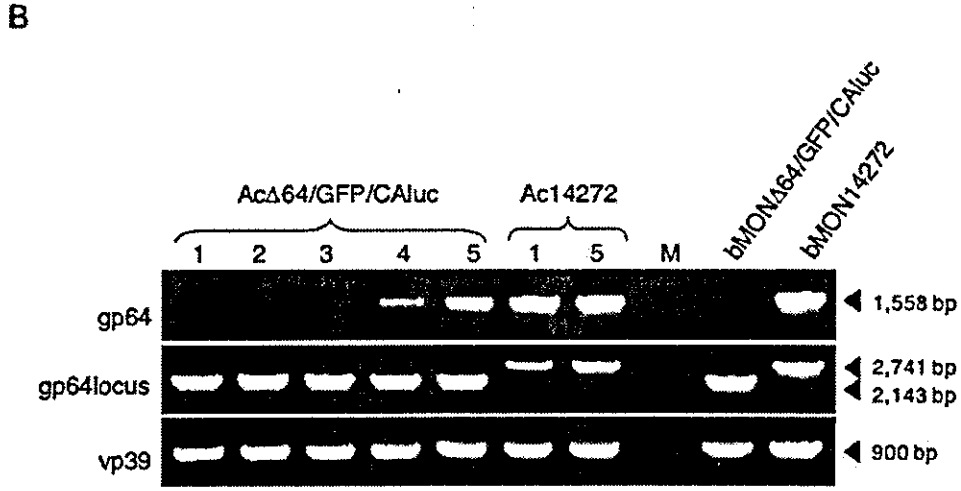


FIG. 2. Appearance of replication-competent viruses incorporating the gp64 gene during passage in Sfgp64 cells. (A) Sfgp64 cells were transfected with bMONΔ64/GFP/CAluc. Culture supernatants were harvested 4 days after transfection and then serially passaged in Sfgp64 cells at 4-day intervals. Each culture supernatant from Sfgp64 cells was passaged two more times in Sf9 cells to detect the appearance of replication-competent viruses. GFP expression in Sf9 cells was examined by fluorescence microscopy 4 days after infection. (B) PCR analysis of purified virus particles from the supernatant of each Sfgp64 cell passage. The gp64 gene was detectable in particles obtained from the third or later passages. The numbers above the lanes represent the passage numbers. The bMONΔ64/GFP/CAluc and bMON14272 bacmids and Ac14272, generated from bMON14272 and passaged in Sfgp64 cells, were used as controls. M is the culture supernatant of uninfected Sfgp64 cells concentrated under the same conditions as the virus particles. The primers amplified fragments as detailed in the legend to Fig. 1.

were expressed in the cells transfected with the appropriate bacmids. The proteins were also detected in the purified AcΔ64/VSVG/CAluc and AcΔ64/gp64/CAluc viruses, respectively, but not in AcΔ64/GFP/CAluc.

To assess the efficacy of mammalian cell gene transduction by the pseudotype baculoviruses, 293T and BHK cells were inoculated with various amounts of pseudotype viruses (Fig. 4B). Similar levels of reporter gene expression were observed in a dose-dependent manner in both cell lines following infection with AcΔ64/gp64/CAluc and AcΔ64/VSVG/CAluc. AcΔ64/GFP/CAluc, however, was unable to infect either cell line. To confirm the role of gp64- or VSVG-mediated gene transduction into mammalian cells by the pseudotype baculoviruses, we attempted to neutralize 293T cell infection using

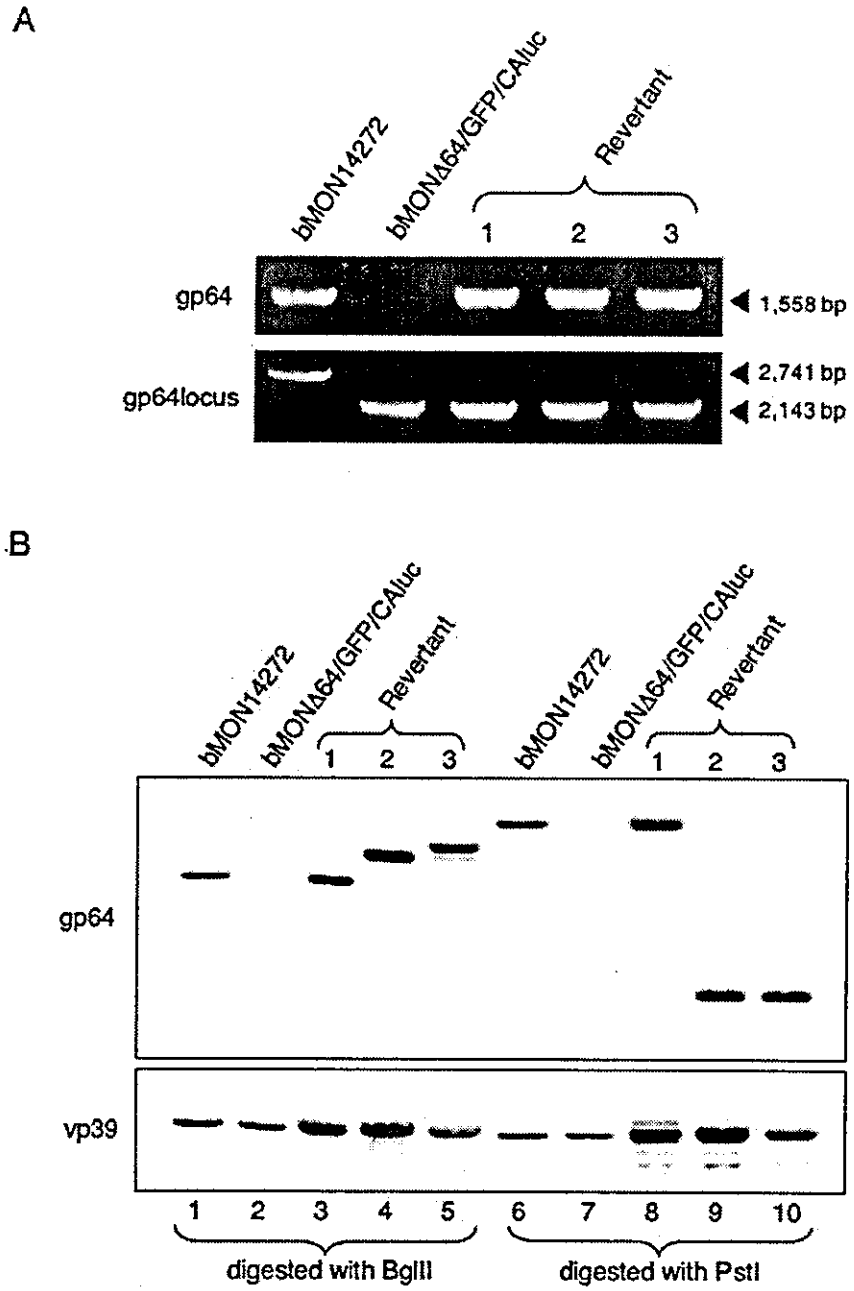

FIG. 3. Incorporation of the gp64 gene into gp64-null baculovirus genomes by nonhomologous recombination. (A) PCR analysis of three independent revertant viruses. In each revertant virus, the gp64 gene and gp64 locus primer pairs produced 1,558- and 2,143-bp fragments, respectively, indicating the presence of the mutant gp64 locus. (B) Southern blot analysis of revertant viruses. Viral DNA was digested with BglII or PstI, separated, and hybridized to gp64- or vp39-specific probes. Fragments containing the gp64 gene were detectable in all of the revertant viruses, but the fragment sizes differed. The vp39 gene, used as an internal control, was detectable in all revertant DNAs and bacmids. The numbers above the lanes represent the revertant clones. The bMONΔ64/GFP/CAluc and bMON14272 bacmids were used as controls.

specific monoclonal antibodies against gp64 and VSVG. Luciferase expression in 293T cells infected with either AcΔ64/gp64/CAluc or AcΔ64/VSVG/CAluc was specifically inhibited by antibodies against gp64 or VSVG, respectively (Fig. 4C). These results indicate that reporter gene expression in mammalian cells inoculated with pseudotype baculoviruses relies on the interactions mediated by the ligand proteins on the viral particles.

Ligand-directed gene targeting by pseudotype baculovirus. To demonstrate the ligand-directed gene transduction of target cells by pseudotype baculoviruses, we constructed pseudotype viruses bearing CD46 or SLAM in place of the gp64

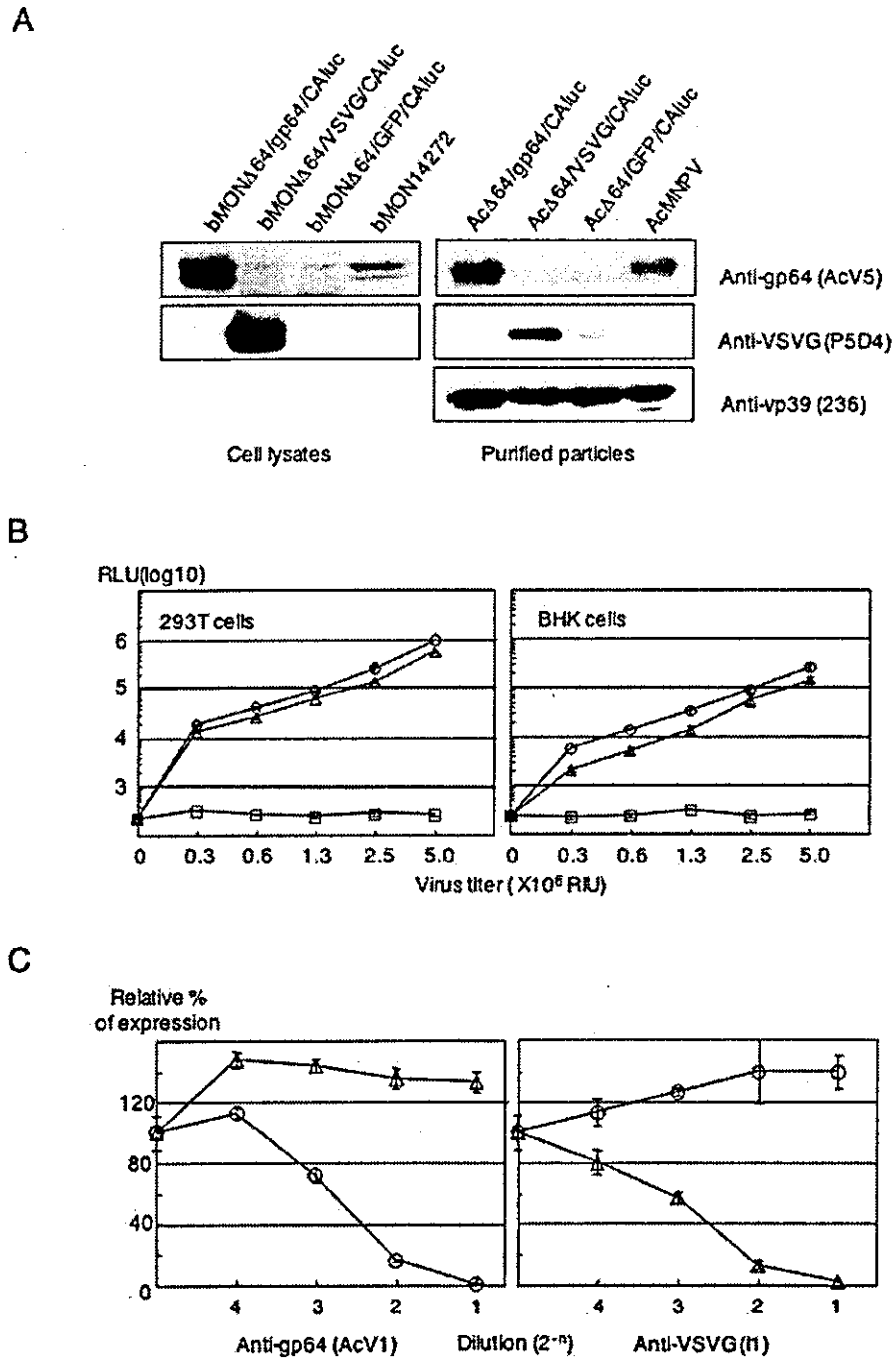

FIG. 4. Characterization of pseudotype baculoviruses bearing VSVG. (A) VSVG and gp64 expression in Sf9 cells transfected with the bMONΔ64/gp64/CAluc, bMONΔ64/VSVG/CAluc, bMONΔ64/GFP/CAluc, or bMON14272 bacmid were examined by Western blot analysis using monoclonal antibodies specific for VSVG (P5D4) and gp64 (AcV5) (left). The incorporation of gp64 and VSVG into pseudotype particles, AcΔ64/gp64/CAluc, AcΔ64/VSVG/CAluc, AcΔ64/GFP/CAluc, or AcMNPV, was examined by Western blot analysis using monoclonal antibodies specific for gp64, VSVG, and vp39 (236) (right). (B) Gene transduction into mammalian cells by pseudotype baculoviruses. 293T or BHK cells (3×10^4) were inoculated with various amounts of AcΔ64/gp64/CAluc, AcΔ64/VSVG/CAluc, or AcΔ64/GFP/CAluc. The pseudotype titers are expressed as RIU. Luciferase expression was determined 24 h after infection. The results shown are the means of three independent assays, while the error bars represent the standard deviations. RLU, relative light units. (C) Neutralization of gene transduction into mammalian cells by pseudotype baculoviruses by antibodies specific for the particle ligands. AcΔ64/gp64/CAluc or AcΔ64/VSVG/CAluc (10^6 RIU) was preincubated with the indicated dilutions of monoclonal antibodies specific for gp64 (AcV1) or VSVG (I1), respectively, for 60 min at 37°C. Residual activity, determined as luciferase expression in 293T cells 24 h postinfection, is expressed as the relative percentages of expression. The results shown are the means of three independent assays, with the error bars representing the standard deviations.

protein. The receptor usage of measles virus has been well characterized; while laboratory strains of measles virus, such as the Edmonston strain, can use either CD46 or SLAM as receptors, wild-type strains, such as the Ichinose strain, can only use SLAM for entry (15, 24, 42, 48, 67). Expression of these receptor molecules in Sf9 cells transfected with the bMONΔ64/CD46/CAluc or bMONΔ64/SLAM/CAluc bacmid (Fig. 1B) and subsequent incorporation of the receptors into progeny particles (AcΔ64/CD46/CAluc and AcΔ64/SLAM/CAluc, respectively) were confirmed by Western blotting (Fig. 5A). CD46 was detected in cells transfected with bMONΔ64/CD46/CAluc and in the purified particles of AcΔ64/CD46/CAluc, whereas SLAM was detected in cells transfected with the bacmid but not in the particles of AcΔ64/SLAM/CAluc.

The gp64, CD46, and SLAM proteins are all type I membrane proteins. SLAM has a 77-amino-acid cytoplasmic domain (23), while gp64 and CD46 have only 7- and 33-amino-acid tails, respectively (49, 60). Therefore, we speculated that SLAM may be only inefficiently incorporated into baculovirus particles, due to its large cytoplasmic domain. To examine the effect of the cytoplasmic domain length on incorporation into baculovirus particles, we constructed a mutant SLAM molecule, SLAMcyto7, with a deletion in the C-terminal cytoplasmic domain that preserves only the seven membrane-proximal amino acids. Western blot analysis revealed that SLAMcyto7 was efficiently expressed in Sf9 cells transfected with bMONΔ64/SLAMcyto7/CAluc and subsequently incorporated into AcΔ64/SLAMcyto7/CAluc particles at levels similar to those seen for CD46 inclusion into AcΔ64/CD46/CAluc (Fig. 5A).

To determine the efficiency of ligand-directed gene delivery, BHK cells were cotransfected with expression plasmids encoding the measles virus H and F glycoproteins of the Edmonston (EdH and EdF) or Ichinose (IcH and IcF) strain. These cells were inoculated with pseudotype baculoviruses (Fig. 5B). AcΔ64/CD46/CAluc exhibited gene delivery specifically to cells expressing EdH and EdF, but not IcH and IcF. Although the efficiency of gene transduction was 10 times lower than that seen with AcΔ64/CD46/CAluc, AcΔ64/SLAMcyto7/CAluc could also deliver a reporter gene to cells expressing the Edmonston and Ichinose strain glycoproteins but not to control cells. While AcΔ64/gp64/CAluc and AcΔ64/VSVG/CAluc could effectively deliver a reporter gene to all of the cells examined, AcΔ64/SLAM/CAluc was ineffective against all of the cell lines tested, likely due to the lack of SLAM incorporation into the virions.

To confirm ligand-directed gene delivery by AcΔ64/CD46/CAluc and AcΔ64/SLAMcyto7/CAluc to cells expressing appropriate measles virus glycoproteins, we tested the neutralization of gene transduction by specific monoclonal antibodies against CD46 and SLAM (Fig. 5C). Gene transduction of target cells by either AcΔ64/CD46/CAluc or AcΔ64/SLAMcyto7/CAluc, but not by AcΔ64/gp64/CAluc, could be inhibited in a dose-dependent manner by anti-CD46 and anti-SLAM monoclonal antibodies, respectively. These results indicate that pseudotype baculoviruses can deliver foreign genes to target cells in a ligand-directed manner.

Entry pathway of the pseudotype baculoviruses. Virus entry occurs either by the direct fusion of viral envelope proteins with the host plasma membrane at neutral pH, as seen for measles virus, or following receptor-mediated endocytosis, as seen for AcMNPV and VSV, in which envelope glycoproteins undergo conformational changes into a fusion-competent state, leading to fusion between viral and host membranes at low pH within endosomes (6, 36, 69). Ammonium chloride and chloroquine, which inhibit endosomal acidification, have been used as entry inhibitors for viruses that penetrate cells through receptor-mediated endocytosis (7). To examine the entry pathways used by the pseudotype baculoviruses, we examined the infectivity of AcΔ64/gp64/CAluc, AcΔ64/VSVG/CAluc, and AcΔ64/CD46/CAluc to BHK cells expressing EdH and EdF in the presence or absence of ammonium chloride or chloroquine (Fig. 6). Although these compounds inhibited gene transduction of BHK cells inoculated with AcΔ64/gp64/CAluc or AcΔ64/VSVG/CAluc in a dose-dependent manner, gene transduction by AcΔ64/CD46/CAluc was not inhibited. In contrast, ammonium chloride treatment enhanced gene expression following AcΔ64/CD46/CAluc infection. These results indicate that the pseudotype baculoviruses utilize entry pathways conferred by the nature of the ligand protein replacing gp64.

Morphology of pseudotype baculovirus. To address any alterations in pseudotype baculovirus morphology, we examined the AcMNPV, AcΔ64/VSVG/CAluc, and AcΔ64/CD46/CAluc virus particles by transmission electron microscopy (Fig. 7A to C). All of the pseudotype baculoviruses exhibited rod shapes and similar sizes, indistinguishable from the wild-type baculovirus. To examine the incorporation of exogenous ligands into the virion, purified AcΔ64/VSVG/CAluc and AcΔ64/CD46/CAluc particles were examined by immunoelectron microscopy using specific monoclonal antibodies against VSVG and CD46 (Fig. 7E and F). In both pseudotype viruses, gold particles were detected on the virion surface from the stalk to the head domains, indicating that VSVG and CD46 were incorporated into the AcΔ64/VSVG/CAluc and AcΔ64/CD46/CAluc virus particles, respectively.

DISCUSSION

Baculovirus is a useful tool for gene delivery to mammalian cells due to the large capacity of the virus to incorporate foreign genes, the wide host range, and the lack of replication in mammalian cells, providing minimal toxicity (29, 53, 55, 61, 68). The gp64 envelope glycoprotein, involved in attachment to both insect and mammalian cells, is required for low-pH-triggered membrane fusion following endocytosis during virus entry (6, 8, 12, 14, 20, 21, 31, 40, 41, 66, 69, 70). We have previously demonstrated that the interaction of gp64 with cell surface phospholipids may be important in baculovirus infection of mammalian cells (66). As the recombinant baculoviruses used for gene delivery to mammalian cells in this system retained the gp64 envelope glycoprotein, it was difficult to deliver foreign genes to specific target cells.

To generate a ligand-directed gene-targeting baculovirus vector, we established a bacmid system to produce recombinant baculoviruses in which the gp64 gene was replaced with other ligand genes of interest. The gp64 protein is required for efficient budding from Sf9 cells; the budding of a mutant virus lacking gp64 was reduced to 2% of that seen for wild-type baculovirus (49). Although AcΔ64/gp64/CAluc, a pseudotype virus in which gp64 was reintroduced into the gp64 deletion mutant, incorporated two to three times as much gp64 protein as seen in wild-type baculovirus (Fig. 4A), the infectious titers

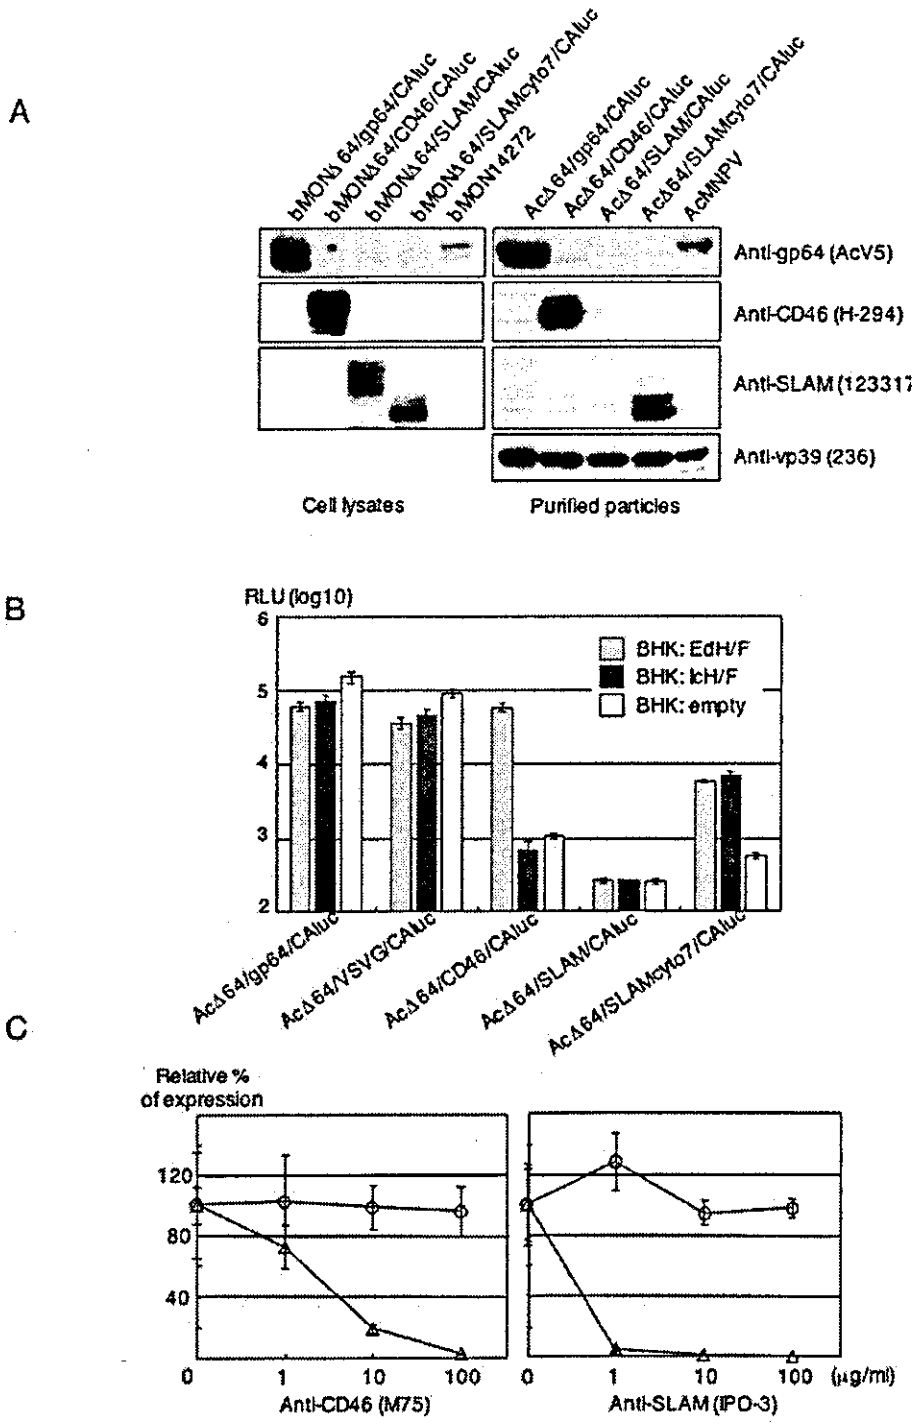

FIG. 5. Ligand-directed gene targeting by pseudotype baculoviruses. (A) The expression of gp64, CD46, SLAM, and SLAMcyto7 in Sf9 cells transfected with the bMONΔ64/gp64/CAluc, bMONΔ64/CD46/CAluc, bMONΔ64/SLAM/CAluc, bMONΔ64/SLAMcyto7/CAluc, or bMON14272 bacmid was examined by Western blot analysis using monoclonal antibodies specific for gp64 (AcV5), CD46 (H-294), and SLAM (123317), as indicated (left). The incorporation of gp64, CD46, SLAM, and SLAMcyto7 into pseudotype particles, AcΔ64/gp64/CAluc, AcΔ64/CD46/CAluc, AcΔ64/SLAM/CAluc, AcΔ64/SLAMcyto7/CAluc, or AcMNPV, was examined by Western blot analysis using monoclonal antibodies specific for gp64, CD46, SLAM, and vp39 (236), as indicated (right). (B) Ligand-directed gene targeting by pseudotype baculoviruses. BHK cells (3×10^4) were co-transfected with expression plasmids encoding measles virus H and F glycoproteins of either the Edmonston (EdH and EdF) or Ichinose (IcH and IcF) strain or with an empty vector and then inoculated with 5×10^6 RIU of AcΔ64/gp64/CAluc, AcΔ64/VSVG/CAluc, AcΔ64/CD46/CAluc, AcΔ64/SLAM/CAluc, or AcΔ64/SLAMcyto7/CAluc 24 h after transfection. Luciferase expression was determined 24 h after infection. The results shown are the means of three independent assays, and the error bars represent the standard deviations. RLU, relative light units. (C) Neutralization of ligand-directed gene targeting by antibodies specific for viral ligands. AcΔ64/gp64/CAluc, AcΔ64/CD46/CAluc, or AcΔ64/SLAMcyto7/CAluc (10^6 RIU) was preincubated with various concentrations of monoclonal antibodies specific for CD46 (M75) or SLAM (IPO-3) for 60 min at 37°C. Residual activity was determined by measurement of luciferase expression in BHK cells expressing the H and F glycoproteins of the Edmonston or Ichinose strain 24 h postinfection. The values are expressed as the relative percentages of expression. The results shown are the means of three independent assays, with the error bars representing the standard deviations.

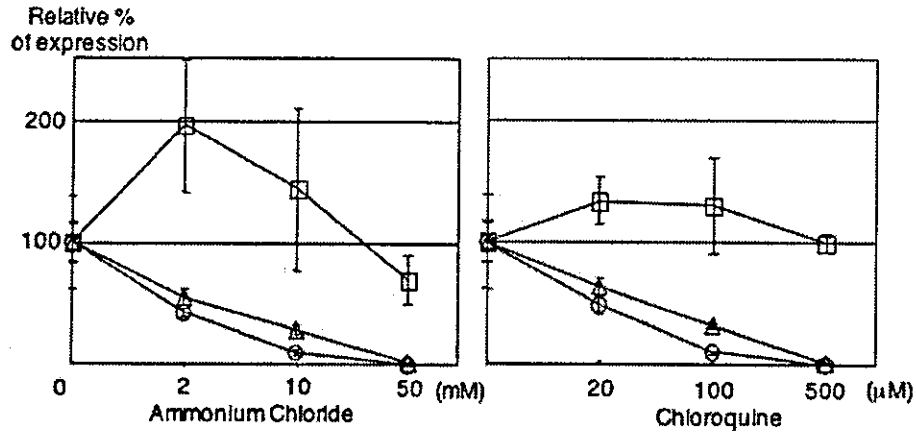

FIG. 6. Effects of lysosomotropic reagents on gene transduction of pseudotype baculoviruses. BHK cells (3×10^4) transfected with expression plasmids encoding the measles virus H and F glycoproteins of the Edmonston strain (EdH and EdF) were pretreated with various concentrations of ammonium chloride or chloroquine for 60 min. The cells were then inoculated with 10^6 RIU of AcΔ64/gp64/CAluc, AcΔ64/VSVG/CAluc, or AcΔ64/CD46/CAluc in the presence of the lysosomotropic reagents. Luciferase expression was determined 24 h postinfection. The results shown are the averages of three independent assays, with the error bars representing the standard deviations.

of the virus, determined by plaque formation in Sf9 cells, were similar. These results suggest that, while the polyhedrin promoter is sufficient to overexpress and incorporate a ligand of interest into the virion, this is not necessarily the best choice to maintain ligand function. The discrepancy between gp64 incorporation and the infectious titer may be attributed to a limited capacity to incorporate functional gp64 into particles and the timing of ligand gene activation. As the polyhedrin promoter is activated in the late stage of infection, baculoviruses budding in the early stage of infection may be unable to incorporate the ligand expressed by the polyhedrin promoter. Use of the immediate-early promoter for ligand expression may improve the efficiency of incorporation into virus particles. In support of this possibility, the infectious titer of a recombinant AcMNPV in which the gp64 gene was replaced with the F gene from *Lymantria dispar* NPV under the control of the polyhedrin promoter was ~60-fold lower than that of a virus with the F gene under the control of the gp64 promoter (33).

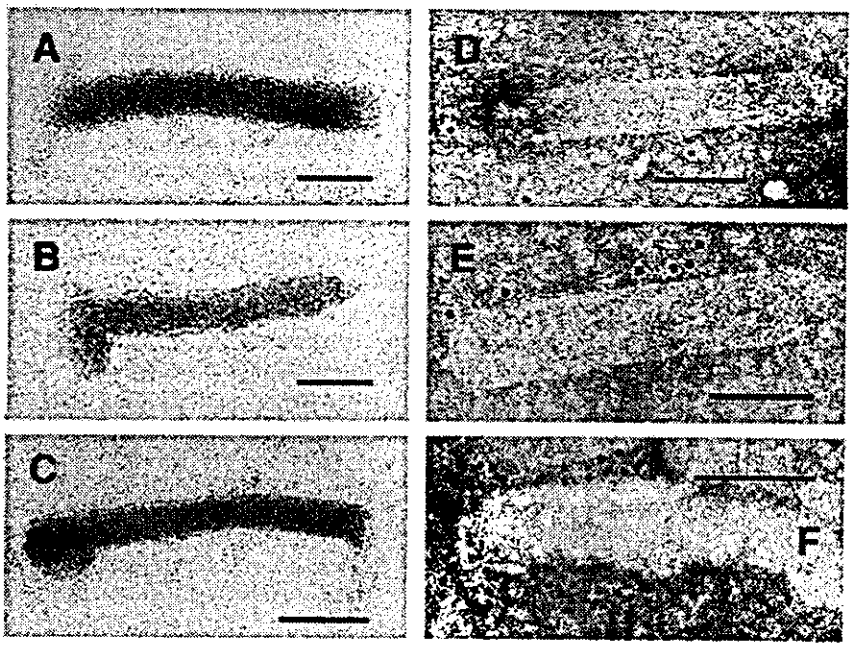

FIG. 7. Electron micrographs of pseudotype baculoviruses. Purified virus particles of wild-type AcMNPV (A), AcΔ64/VSVG/CAluc (B), and AcΔ64/CD46/CAluc (C) were examined by electron microscopy. A typical rod shape was visible in all of the pseudotype baculoviruses. The VSVG or CD46 proteins were observed on the surfaces of AcΔ64/VSVG/CAluc (E) and AcΔ64/CD46/CAluc (F) by immunoelectron microscopy using specific monoclonal antibodies against VSVG and CD46, respectively. AcMNPV treated with the monoclonal antibody against VSVG was used as a control (D). The bars on the panels represent 100 nm.

The replication competency in Sf9 cells of a gp64-null recombinant baculovirus could be rescued by incorporation of the VSVG gene (33, 34). We confirmed that the recombinant baculovirus deleted the gp64 gene and instead incorporated the VSVG gene under the control of the polyhedrin promoter, was replication competent in insect cells, and exhibited a high level of reporter gene transduction into 293T and BHK cells. The compatibility of VSVG in this system may result from similarities of the structural and functional characteristics of VSVG to those of gp64; both proteins are type I membrane glycoproteins, exist in trimeric complexes, and are capable of inducing membrane fusion at low pHs (6, 50, 54). Although the recombinant baculovirus in which gp64 is replaced with VSVG is able to replicate in insect cells and transduce foreign genes into a wide variety of mammalian cells, VSVG was suggested to recognize phosphatidylserine (58) or other ubiquitously expressed molecules other than phosphatidylserine (13) as a receptor(s), making it difficult to confer cell type specificity to gene delivery using VSVG pseudotype baculoviruses.

To establish ligand-directed gene delivery by pseudotype baculoviruses, it is necessary to propagate replication-deficient pseudotype baculoviruses possessing a ligand of interest in Sfgp64, a replication-competent cell line stably expressing gp64. After three rounds of passage of the pseudotype virus in Sfgp64 cells, however, replication-competent revertant viruses that had incorporated the gp64 gene were generated. Sfgp64 cells were established by transfection of Sf9 with a plasmid encoding the gp64 gene lacking any flanking sequences. Southern blot analysis revealed that the gp64 gene was integrated into the genomes of the baculovirus revertants by nonhomologous recombination. Homologous recombination between the AcMNPV genome and either a transfer vector (32, 38), additional AcMNPVs (19), or *B. mori* NPV can occur in insect cells with high frequency (27, 28). In contrast, our data suggest that the revertant viruses were not generated by homologous recombination but by nonhomologous incorporation of the gp64 gene from the Sfgp64 chromosome into the viral genome. Nonhomologous recombination between plasmid DNA and the baculovirus genome was previously reported upon cotransfection into insect cells (71). A gp64-null virus could propagate in $Sf9^{Op1D}$ cell lines constitutively expressing OpNPV gp64 without incorporating the gp64 gene into the viral genome (33, 34). One possible explanation for our result may be the difference between the gp64 genes of OpNPV and AcMNPV. Although the Sfgp64 cell line was established by sorting cells expressing a high level of gp64 on the cell surface, the expression level of gp64 might be lower than that of the $Sf9^{Op1D}$ cell line, and the lower level of expression of gp64 might result in the selective amplification of revertants. To circumvent the high-frequency incorporation of foreign DNA into the baculoviral genome, we attempted the lipofection of recombinant bacmids into Sf9 cells instead of amplification of pseudotype baculoviruses in Sfgp64. Although it is not possible to obtain a high pseudotype virus titer by this method, we can generate pure virus stocks without any contaminating replication-competent baculoviruses incorporating the gp64 gene. To prepare a high-titer stock of a replication-deficient pseudotype baculovirus carrying a foreign ligand, however, it is essential to propagate the pseudotype virus in Sf9 cells expressing gp64 without the transfection of plasmid DNA. Expression of gp64 by RNA transfection, RNA viral vectors, or the RNA replicon system may be able to avoid the incorporation of gp64 DNA into the baculovirus genome.

We constructed a pseudotype baculovirus, AcΔ64/CD46/CAluc, bearing human CD46 in place of gp64 on viral particles. CD46 is a multifunctional protein involved in the infection of various microorganisms and the regulation of complement activation (10). CD46, also known as membrane cofactor protein, protects autologous cells from complement attack by serving as a cofactor for factor I-mediated inactivation of C3b and C4b, blocking the complement cascade at C3 activation (2). CD46 also serves as a receptor for human herpes virus 6 (56), group B adenovirus (17, 59, 62), bovine viral diarrhea virus (39), two bacterial strains (*Streptococcus pyogenes* and pathogenic *Neisseria*) (26, 46), and the Edmonston strain of measles virus (15, 42). In this study, we demonstrated that AcΔ64/CD46/CAluc exhibited specific reporter gene transfer to and expression in BHK cells expressing the measles virus H and F glycoproteins of the Edmonston strain but not those expressing the Ichinose strain glycoproteins that require SLAM as a receptor (67). Therefore, a CD46 pseudotype baculovirus bearing a suicide gene may be able to eliminate cells expressing pathogen ligands that utilize CD46 as a receptor. Furthermore, CD46 is frequently overexpressed on cancer cells, possibly serving as a mechanism to overcome lysis by complement (16). In support of the potential utility of this vector, the Edmonston strain of measles virus has a potent and selective oncolytic activity (52). CD46 pseudotype baculovirus may also be applicable for the clearance of tumor cells surviving oncolytic measles virus treatment.

Infections with AcΔ64/gp64/CAluc and AcΔ64/VSVG/CAluc, carrying gp64 and VSVG on the particles, respectively, could be decreased by treatment with ATPase inhibitors, chloroquine, or ammonium chloride, while AcΔ64/CD46/CAluc was resistant to treatment. This finding suggests the possibility of constructing a baculovirus vector capable of both targeting and modulating the viral entry pathway, as seen for VSV (7). This is different from influenza virus vectors, where acidic exposure within endosomes is critical for the dissociation of the matrix protein from the ribonucleocapsid (9, 37). In contrast to AcΔ64/CD46/CAluc, AcΔ64/SLAM/CAluc could not incorporate the full-length SLAM molecule into particles, preventing specific gene transduction. The inability to mediate gene delivery was not due to the absence of an interaction with specific targets, as Sf9 cells expressing SLAM induced membrane fusion with BHK cells expressing the H and F glycoproteins of either the Edmonston or Ichinose strain of measles virus (data not shown). The ligands incorporated efficiently into baculovirus particles, including gp64, VSVG, and CD46, all have relatively short cytoplasmic domains, measuring 7, 29, and 33 amino acids in length, respectively (49, 54, 60). In contrast, SLAM possesses a cytoplasmic tail of 77 amino acids (23). We therefore hypothesized that the length of the ligand cytoplasmic domain may be critical for efficient incorporation into baculovirus particles. AcΔ64/SLAMcyto7/CAluc, possessing a mutant SLAM molecule with the C-terminal 70 amino acids of the cytoplasmic domain deleted, efficiently incorporated the mutant SLAM into particles and exhibited specific gene delivery to BHK cells expressing the H and F glycoproteins of both measles virus strains. Although the mechanism by which SLAM

incorporation into baculovirus particles is enhanced by C-terminal truncation of the cytoplasmic domain is not known, one possibility might be a change in SLAM localization. The gp64 protein localizes to the cell surface but is excluded from lipid raft microdomains (72). As VSVG and CD46 also do not associate with lipid rafts (35, 57), proteins localized to lipid raft microdomains may be excluded during virus assembly and budding. Although the cellular localization of SLAM is not known, further studies will be necessary to clarify the relationship between cell surface localization and incorporation into baculovirus particles and to test the involvement of lipid raft microdomains in this process.

Mangor et al. demonstrated that gp64-null baculoviruses pseudotyped with VSVG were not morphologically distinguishable from budded wild-type AcMNPV particles (34). We confirmed that AcΔ64/VSVG/CAluc, as well as AcΔ64/CD46/CAluc and AcΔ64/GFP/CAluc, exhibited a morphology similar to that of AcMNPV. These results indicate that expression of gp64 is not required for the morphogenesis of a rod-shaped structure for budded AcMNPV particles. Immunogold labeling of AcΔ64/VSVG/CAluc and AcΔ64/CD46/CAluc revealed that the VSVG and CD46 proteins were incorporated into and distributed throughout the whole viral surface. These results are consistent with previous observations that VSVG fusion proteins were distributed throughout the stalk and head domains of baculovirus particles, in contrast to gp64, which was primarily localized in the head domain (11, 44).

In this study, we have demonstrated the capability for ligand-directed gene delivery by pseudotype baculoviruses in vitro. For future in vivo applications of baculovirus vectors for gene targeting to specific organs or virus-infected cells as a method of treatment of inherited or infectious diseases, it is imperative to exhaustively study the transcription of baculoviral genes in mammalian cells for certification of safety. In addition, further studies are needed to establish replication-competent cell lines capable of supporting the propagation of pseudotype viruses without the possibility of replication-competent virus breakthrough by incorporation of gp64 and to optimize the conditions necessary for the efficient incorporation of ligands into recombinant baculovirus particles.

ACKNOWLEDGMENTS

We thank T. Seya and Y. Yanagi for kindly providing CHO cell lines; P. Faulkner, G. F. Rohrmann, and M. A. Whitt for their generous donation of antibodies; and H. Bando and K. Takeuchi for providing plasmids. We also thank H. Murase and I. Yanase for secretarial work and S. Ogawa for technical assistance.

Summary

Recombinant hepatitis E virus capsid protein (HEV CP) assembles orally immunogenic virus-like particles (VLP) when expressed in an insect cell system. We used plant expression cassettes, pHEV101 and pHEV110, for transformation of potato to express HEV CP, and 10 independent transgenic lines of HEV101 and 6 lines of HEV110 were obtained. ELISA for HEV CP was performed on tuber extracts. Accumulation of HEV CP in tubers varied from about 5 to 30 μg/g fresh tuber depending on the transgenic plant line. We further compared the expression levels with the yield of tubers for each line. Tuber yield varied less than expression levels, and ranged from about 600 to 1000 g per pot. Although Western blot showed that apparently intact HEV CP accumulated, we observed very limited assembly of virus-like particles in potato tubers. Oral immunization of mice with transgenic potatoes failed to elicit detectable anti-CP antibody response in serum, suggesting that VLP assembly is a key factor in orally delivered HEV CP vaccines.

Keywords: Hepatitis E; HEV; VLP; Transgenic potato

1. Introduction

Hepatitis E virus (HEV) is a causative agent of hepatitis E that occurs in many developing countries [1], and this virus is currently classified into a tentative genus, "Hepatitis E-like viruses." HEV is transmitted mainly by the fecal-oral route, and large epidemics due to this virus are often associated with contaminated water [2,3]. Hepatitis E has been formerly known as an enterically transmitted non-A, non-B hepatitis [4]. The fact that HEV can survive in the intestinal tract suggests that the virus is relatively stable to acid and mild alkaline conditions.

HEV contains a single-stranded positive-sense approximately 7.5 kb RNA molecule that is 3′ polyadenylated and includes three open reading frames (ORFs). ORF1, mapped in the 5′ half of the genome, is thought to encode viral nonstructural proteins. ORF2, located at the 3′-terminus of the genome, encodes a 72 kDa protein for the putative viral capsid. ORF3, with unknown function, is mapped between ORF1 and ORF2 [5]. In the absence of an appropriate cell culture for HEV propagation, research has focused on the expression of the ORF2 protein in heterologous systems. Recently, virus-like particles (VLP) of recombinant hepatitis E virus (rHEV) were produced by using a baculovirus system carrying an N-terminally truncated *ORF2* gene of the Burma strain [6]. Thus, rHEV VLP were formed in Tn5 cells and could be collected from the culture supernatant.

In order to evaluate the potential of rHEV VLP as an oral immunogen, we analyzed the immune responses in mice and monkeys after oral administration [7,8]. The animals were orally inoculated with purified rHEV VLP without adjuvant. ELISA indicated that oral immunization with rHEV VLP induced immune responses in both mice and monkeys. In addition, the monkeys were completely protected from infection when challenge was carried out with native HEV, suggesting that rHEV VLPs are a potential mucosal vaccine for HEV infection.

For expression and delivery of recombinant subunit vaccine antigens including Norwalk virus capsid protein (NVCP), transgenic plants have been created [9]. Clinical trials using potatoes expressing NVCP showed very promising results, with 19 of 20 volunteers showing immune responses against NVCP delivered by ingestion of raw transgenic potatoes containing approximately 500 μg antigen per dose [10]. Previous studies with NVCP expression in tobacco and potato cells demonstrated that subunits assembled to form VLP very similar to those obtained with baculovirus-infected insect cell expression, although up to 75% of the antigen was present as monomers or partially assembled aggregates [9]. VLP assembly may be important for obtaining stability against acid and protease-mediated degradation in the stomach, as well as for presentation of conformation-dependent epitopes that may be needed for effective virus neutralization.

In this study, we expanded our effort to create transgenic plants that express HEV capsid proteins (HEV CP).

2. Materials and methods

2.1. Preparation and purification of rHEV VLP

The molecular cloning and construction of a recombinant baculovirus Ac5480/7126 harboring the HEV capsid protein gene lacking 111 amino acids at the N-terminal were described previously [6]. The rHEV VLP were prepared using Tn5 cells infected with Ac5480/7126 at a multiplicity of infection of 10. Following 7 days of incubation at 26.5 °C, intact cells and cell debris were removed from the culture medium, and the rHEV VLP were concentrated by centrifugation and purified by isopycnic binding in CsCl gradient. A visible band containing rHEV VLP was collected, and the rHEV VLP were diluted and pelleted by centrifugation.

2.2. Western blot assay

Leaf samples were extracted by FastPrep (speed 5, 30 s) in 4 ml/g leaf of 50 mM sodium phosphate pH 6.6, 50 mM NaCl, 50 mM sodium ascorbate, 1 mM EDTA, 1 mM PMSF, 0.1% Triton X-100, and clarified for 2 min at 4 °C in microcentrifuge. Aliquots were subjected to SDS-PAGE, blotted to PVDF membrane, and probed with guinea pig anti-HEV (1:1000), visualized with ECL+ (anti-guinea pig IgG-HRP 1:5000) on STORM scanner.

2.3. Antigen-capture ELISA

Potato leaf or tuber extracts were prepared as described above in Section 2.2. Microtiter plates were coated with 50 μl per well of rabbit anti-HEV serum diluted 1:10,000 in carbonate/bicarbonate coating buffer overnight at 4 °C. Insect cell-derived HEV VLP reference standard was diluted in PBST/1% dry milk at 100 ng/ml and two-fold dilutions down to 3.125 ng/ml. Leaf or tuber extracts were diluted 25- and 50-fold in PBST/1% dry milk. The reference standards and plant extracts were loaded at 50 μl per well and incubated at 37 °C for 1 h. Wells were washed with PBST and then probed with guinea pig anti-HEV serum diluted 1:5000, followed by goat anti-guinea pig IgG-HRP conjugate (Sigma) diluted 1:5000. Color was developed using TMB substrate solution for 5 min.

2.4. Construction of plant expression vector

Intermediate plant expression cassettes were constructed using a vector pIBT210 [11]. Since two truncated forms

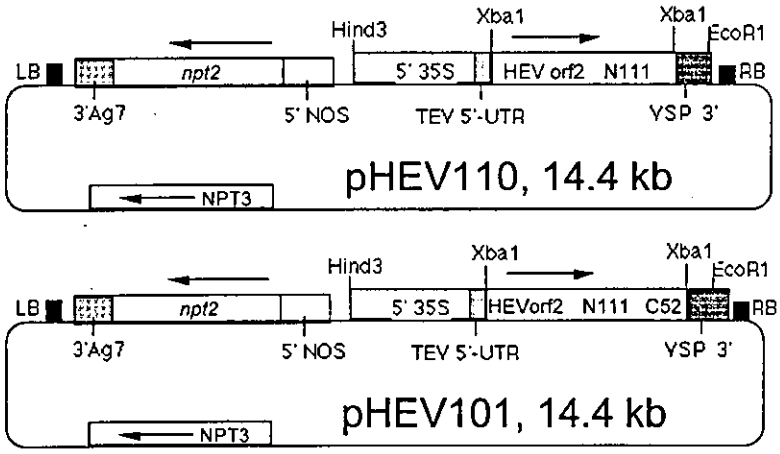

Fig. 1. Plant transformation vectors for expression of HEV CP. Binary T-DNA plasmid vectors, pHEV101 and pHEV110, for expression of HEV CP, p54 and p58, are shown. They contain left border (LB) and right border (RB) sequence motifs that delineate the DNA to be transferred (T-DNA) and integrated into nuclear chromosomal DNA. Within the T-DNA borders lies a selectable marker (*ntp2*), which confers resistance to the antibiotic kanamycin, and will allow specific regeneration of transformed plants. Also included are expression cassettes for HEV CP, which are driven by the constitutive CaMV 35S promoter linked to the tobacco etch virus (TEV) 5′-UTR, which acts as a translational enhancer, and terminated by the soybean VSP 3′ end [9].

of HEV ORF2 appeared to yield VLP assembly in insect cells (ΔN111 and ΔN111/ΔC52), we inserted these into pIBT210. Then, the expression cassettes were transferred into a binary vector (pGPTV-Kan) for use in *Agrobacterium*-mediated delivery of foreign DNA into plant cells. These constructs, pHEV101 (ΔN111/ΔC52) and pHEV110 (ΔN111), are shown in Fig. 1.

3. Results

3.1. Characterization of rHEV

The capsid proteins of HEV with its N-terminal 111 amino acids truncated were expressed with a recombinant baculovirus in insect cells, where the capsid proteins self-assembled into VLP [6]. The rHEV VLP were purified by centrifugation and characterized by SDS-PAGE and Western blot assay, where a major protein band with a molecular weight of 54 kDa was observed. The particles possess antigenicity similar to that of authentic HEV particles and consequently they appear to be a good antigen for the sensitive detection of HEV-specific IgG and IgM antibodies [12]. Furthermore, the VLP may be the most promising candidate for an HEV vaccine owing to its potent immunogenicity [7,8]. Therefore, we used the same construct to express HEV CP in the transgenic plant.

3.2. Coding sequence analysis

We first examined the coding sequence for the HEV CP to determine whether the nucleotide sequence should be altered for optimization of plant expression. Codon use is fairly favorable to both dicot and monocot plants. Of 660 total codons, 3.6% are monocot-unfavorable and 12.8% are dicot-unfavorable, defined as either making up less than 10% of codon choice for that amino acid or less than one third the frequency of the most popular codon for that amino acid, inclusive.

3.3. Expression in potato plants

We used pHEV101 and pHEV110 for transformation of potato "Desiree" as described [9,13]. After regeneration of multiple independent kanamycin-resistant lines, we screened leaf samples by ELISA for HEV CP expression. Expression levels ranged up to approximately 0.33% total soluble protein, which is similar to the levels we obtained for NVCP [9]. There was no apparent difference in expression from either construct pHEV101 (ΔN111/ΔC52 coding sequence) and pHEV110 (ΔN111 coding sequence) as the range and maximal expression were similar for both.

We selected the best lines for transplant to the greenhouse and after 2 months growth we assayed leaves for expression of HEV CP by ELISA. We observed that the antigen

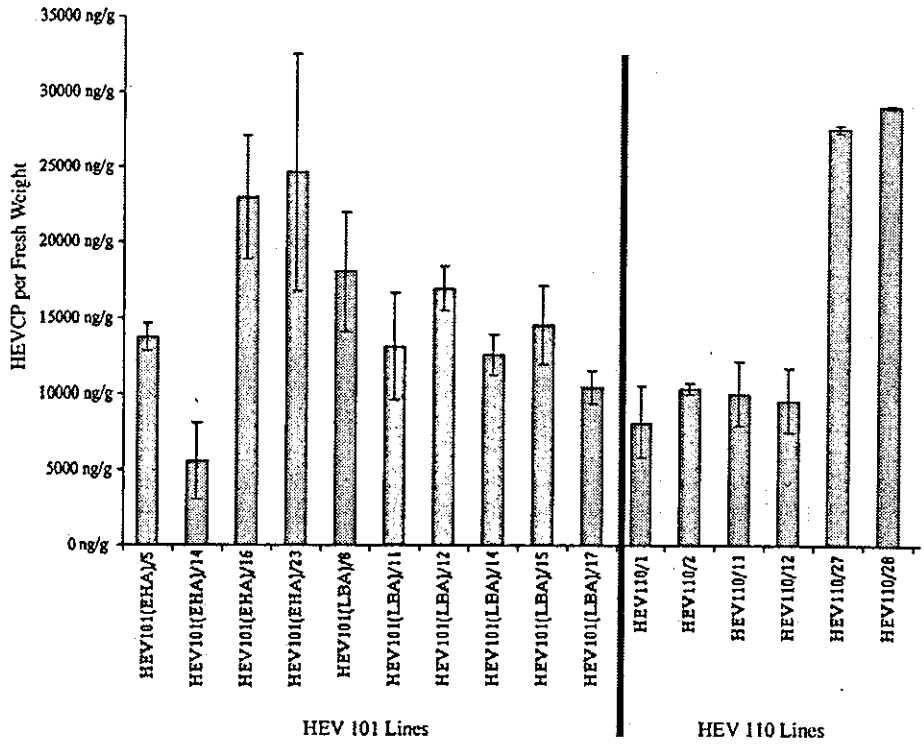

Fig. 2. Expression of HEV CP in tubers of transgenic potato lines. HEV101 (10 lines) or HEV110 (6 lines) tubers were extracted and assayed by ELISA for HEV CP. Error bars indicate standard error for three different tubers from the same line.

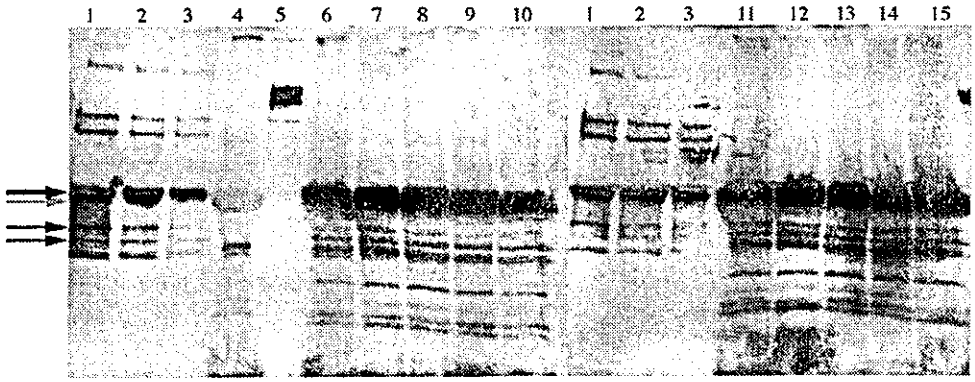

Fig. 3. Western blot of HEV CP expressed in potato leaves. Leaf samples were extracted by FastPrep and clarified by centrifugation. Aliquots were subjected to SDS-PAGE, blotted to PVDF membrane, and probed with guinea pig anti-HEV, visualized with ECL+ on STORM scanner. Lanes are: (1) 50 ng HEV VLP from baculovirus-infected insect cells, (2) 25 ng HEV VLP, (3) 12.5 ng HEV VLP, (4) untransformed Desirée extract, (5) BioRad Kaleidoscope Molecular Weight Marker, (6) HEV101(EHA)/5, (7) HEV101(EHA)/12, (8) HEV101(EHA)/16, (9) HEV101(EHA)/17, (10) HEV101(LBA)/11, (11) HEV101(LBA)/14, (12) HEV110/1, (13) HEV110/2, (14) HEV110/11 and (15) HEV110/12. Bold arrow indicates major band of VLP sample that corresponds to the 54 kDa HEV CP; thin arrows indicate products of proteolysis.

expression on a total protein basis was reduced four- to five-fold compared to that in tissue-cultured plantlets. This is not unexpected, since soil-grown plants in natural light have higher levels of total leaf protein. Further, it is possible that the recombinant antigen is less stable in the soil-grown plants.

3.4. HEV CP expression in potato tubers

Ten independent transgenic lines of HEV101 and six lines of HEV110 were grown to maturity in the greenhouse and tubers were harvested and washed. ELISA for HEV CP was performed on tuber extracts as described for leaf extracts. Accumulation of HEV CP in tubers varied from about 5 to 30 μg/g fresh tuber, depending on the transgenic plant line (Fig. 2). This compares well with the expression of NVCP in potato tubers [9] and is better than expression of *E. coli* LT-B protein in potato [13]. We further compared the expression levels with the yield of tubers for each line. Tuber yield varied less than expression levels, and ranged from about 600 to 1000 g per pot. We used these data to select lines HEV101-16, HEV101-23, HEV110-27, and HEV110-28 for highest yields of recombinant protein.

Western blot of transgenic potato leaf extract showed that most of the recombinant HEV CP accumulated as 54 kDa, similar to the insect cell-derived antigen (Fig. 3). Some apparent proteolytic products of lower M_r were observed in both insect cell- and potato-derived material. HEV CP in plants transformed with either HEV101 or HEV110 showed similar patterns, with no qualitative or quantitative differences apparent. Failure to detect a larger protein for the single-truncation HEV101 (ΔN111) than that observed for the double truncation HEV110 (ΔN111/ΔC52) suggests that the ΔC52 truncation may occur in planta via an endogenous protease.

4. Discussion

HEV CP has been expressed in baculovirus-infected insect cell system and shown to assemble VLP [6,14]. The VLP have several advantages for the mucosal immunogen as follows: (1) rHEV VLP are composed of a single protein assembled into particles without nucleic acid. (2) rHEV VLP are easy to prepare and purify in a large quantities, approximately 1 mg per 2×10^7 insect cells. (3) rHEV VLP are antigenically similar to the native virion. (4) rHEV VLP are highly immunogenic in experimental animals when injected parenterally.

Our goal is to create transgenic plants that express HEV CP in edible tissues as VLP, in order to obtain an economical oral vaccine. It is likely that the success of oral delivery using VLP from insect cells is due to the particulate structure of the antigen, which contributed either to enhanced resistance to degradation in the gut or to enhanced uptake into the gut immune system.

In our studies with potato expressing HEV CP, we found very few VLPs, with the great majority of ELISA-positive antigen remaining near the top of a sucrose gradient (data not shown). Oral immunization of mice with potatoes expressing HEV CP failed to elicit detectable antibody responses in serum (data not shown). We extracted fecal pellets on day 18 after oral immunization on day 17 to evaluate the content of ELISA-reactive HEV capsid protein. Substantial antigen (3–4% of the dose) was present in pellets of mice that were fed HEV CP potato or gavaged with insect cell-derived VLP. Thus, the potato cells probably provided some protection to the soluble HEV CP present in potato tubers, and perhaps even limited uptake of antigen that may have been present as VLP. Since orally delivered insect cell-derived VLPs stimulated antibody responses and protected monkeys against HEV challenge [8], it is likely that poor VLP assembly in potato

was a major factor in the lack of oral immunogenicity of potato-derived HEV CP in mice. Future studies should focus on the optimization of VLP assembly in plant tissues, which may involve alternative plant host systems, and/or tissue and subcellular targeting of antigen.

Delivery of foreign genes to the digestive tract mucosa by oral administration of nonreplicating gene transfer vectors would be a very useful method for vaccination and gene therapy. However, there have been few reports on suitable vectors. In the present study, we found that plasmid DNA can be packaged in vitro into a virus-like particle (VLP) composed of open reading frame 2 of hepatitis E virus, which is an orally transmissible virus, and that these VLPs can deliver this foreign DNA to the intestinal mucosa in vivo. The delivery of plasmid DNA to the mucosa of the small intestine was confirmed by the results of immunohistochemical analyses using an expression plasmid encoding human immunodeficiency virus env (HIV env) gp120. After oral administration of VLPs loaded with HIV env cDNA, significant levels of specific IgG and IgA to HIV env in fecal extracts and sera were found. Moreover, mice used in this study exhibited cytotoxic T-lymphocyte responses specific to HIV env in the spleen, Payer's patches and mesenteric lymph nodes. These findings suggest that VLPs derived from orally transmissible viruses can be used as vectors for delivery of genes to mucosal tissue by oral administration for the purpose of DNA vaccination and gene therapy.

Introduction

The successful outcome of novel gene therapies and DNA vaccinations largely depends on the development of effective delivery systems.[1] In human applications, both the efficacy and safety of any delivery system used for gene transfer are major concerns. It has been shown that tissue-specific gene transfer by a viral vector could be achieved naturally and effectively through cell specificity of the virus receptors.[2] However, there is a risk of vector toxicity through viral infection of the host cells. Also, the limited sizes of transgenes often present a serious obstacle. Nonviral vectors, such as liposomes, are safer but do not have a cell-specific targeting component and have limited transduction both *in vitro* and *in vivo*. This limitation has been partly overcome by the development of molecular conjugates consisting of cell-specific ligands that confer cell specificity to nonviral vectors.[3,4]

The development of a system for delivering genes to or conferring immunity to mucosal tissue by oral administration would provide a convenient means for effective treatment or prevention of various human diseases, including cancers, infectious diseases and immunological disorders.[5] Since many pathogenic viruses and bacteria establish their initial infections through the mucosal surface, vaccine strategies that can stimulate mucosal immunity have been widely studied (reviewed in Ogra *et al*[6]). However, there are several difficulties in oral immunization with nonreplicating molecules, such as low pH in the stomach, the presence of proteolytic enzymes in the digestive tract and the presence of physical as well as biochemical barriers associated with the mucosal surface itself.[6]

Among the various nonreplicating molecules, a virus-like particle (VLP), an empty particle with a structure similar to that of an authentic virus particle, offers the possibility of a new approach for vaccine development.[7] It is expected that the VLP structure will provide resistance to severe environments in the digestive tracts and enable specific binding to the mucosal surface if an appropriate VLP is chosen.[8] However, VLPs can induce immune responses to themselves, and this is a problem for using VLPs as a vaccine vector to carry foreign DNA. A system using polyoma virus VP1 VLPs as a carrier of DNA by intranasal administration has been reported.[9] These VLPs work as an adjuvant, since DNA vaccine can induce immune responses by intranasal administration without VLPs. Hepatitis E virus (HEV) is an unclassified calicivirus-like, positive-strand RNA virus that causes
