

comparable information exists for such ratios in the general population. Within the framework of an ecological study, however, the assertion of lung cancer is not straightforward where it is generally accepted that more than 80% of male lung cancer and 45% of female lung cancer are attributable to smoking.³³ There are limited comparable data on historical tobacco consumption that could be feasibly incorporated. Thus the ecological relation between national mortality rates of lung cancer and historical asbestos consumption, with valid adjustment for the concurrent effect of smoking, remains a subject warranting further investigation to improve understanding on the full impact of asbestos.

The independent variable was defined as the national asbestos consumption volume divided by the size of the national population, and thus represented the “average” consumption level of asbestos for each national population. As such, sex, age, job and other attributes of a population or consumed fiber types (e.g., amphiboles, chrysotile) were not accounted for. Whether, and the extent to which, the average *consumption* level represents average *exposure* level is also uncertain. However, this index has been widely used to describe the asbestos situation at national and regional levels^{11,18,34} including in ecological studies reported earlier.^{12,18,19} This provided the premises for us to consider the index as a reasonable surrogate for the average exposure level of a national population.

The dependent variables were the national mortality rates of ARDs for the most recent period with available data. The WHO Mortality Database was updated recently to include 2004 data and provided sex-specific data which were incorporated into our analyses. In general, risks and mortality rates of ARDs are much higher in males, probably due to the fact that males have had higher exposure to asbestos, usually through occupations.³⁵ On the other hand, biological responses to asbestos exposure may differ by sex. Thus regression models for each ARD were

constructed separately based on sex-specific mortality rates. It should be noted, however, that the exposure variable did not account for sex difference because consumption/exposure data cannot be apportioned between sexes.

Data on consumption and mortality were each extracted from a single, authoritative, and widely-used global database. This is likely to have enhanced comparability of data. Nevertheless, the quality of data from developing countries is likely to be poorer than those from developed countries. Because under-recognition of ARDs and lack of statistics on asbestos consumption are more likely in developing countries,^{34,36} a negative bias is surmised. Data points near the original point representing developing countries tended to fall below the regression line, suggesting that such a bias was in effect. On balance, the incorporation of experience of developing countries contributed to a better representation of the global situation with inclusion of data close to the original point (with low consumption and low mortality) allowing a valid interpretation of the intercept.

We used the consumption period 1960–1969, when consumption and production of asbestos is known to have increased massively on most continents.²⁴ The resulting time-difference until mortality in 2000–2004 is 37·5 years on average ranging 31–44 years. This corresponds to the higher consensus values typically reported for latency periods of ARDs. This choice can be justified because our analyses evaluated mortality rather than incidence (i.e., additional time to death is required after occurrence). Moreover, similar relations were generally maintained when data from other but close consumption periods were used, e.g., the adjusted R² ranged 0·16–0·83 when the consumption period of 1950–1979 was applied to the models.

Our study has several strengths, including being a comparative evaluation of a wide range of ARDs, using the maximum possible number of countries in the analyses, allowing a sufficient

latency time, applying age-adjustment to mortality rates for valid comparisons, and weighted by the size of sex-specific national populations in the regression model. A limitation of our study, however, is that we were restricted to analyses that included only those countries for which both consumption and mortality data are available, leading to the preclusion of populous countries such as China, India and Russia. Furthermore, lung cancer as an important contributor in the total ARD burden warrants a separate analytical framework. Thus all findings must be cautiously interpreted within the constraints of an ecological study.

In conclusion, this ecological study incorporating national-level data revealed clear and plausible positive relations between historical asbestos consumption levels and mortality rates of ARDs. These relations were most apparent in males, but were also apparent in females. Historical asbestos consumption alone explained the bulk of the variance in subsequent mortality rates of ARDs. Our results lend support to the notion that all countries should move towards eliminating the use of asbestos.

Conflict of Interest Statements

One of our co-authors (TH) served in the past as a member of the Occupational Safety and Health Committee of the Japan Asbestos Association. However, he has not been paid by the Association since 1996 nor has ever received funding to conduct research on asbestos. Another co-author (SF) works for an NGO which provides support to asbestos victims and advocates the banning of asbestos. **Neither of them have received funding or payment in relation to conducting this research.** We do not believe the involvement of these two co-authors in our paper constitutes conflict of interest (COI). None of the other co-authors, including the first and second, have any potential COI. However, in view of our respect towards COI issues, we felt that

we should disclose any potential COI prior to submission.

Acknowledgement

This research was supported in part by a Grant-in-Aid for “Research of Asbestos in the World” from the Ministry of Health Labor, and Welfare of Japan.
