hyde and stained with 0.5% Oil Red O. The amount of triglyceride was determined by Triglyceride E Test (Wako Pure Chemicals).

RNA Isolation, Northern Blotting, and RT-PCR Analyses. The 3T3-L1 cells were grown in DMEM containing 10% calf serum. The day after the cells became confluent, they were treated with vehicle (dimethyl sulfoxide) only, rosiglitazone (Rosi), TPT, or TBT in DMEM containing 10% FBS and 5 μg/ml insulin. The cells were harvested at various times after treatment, and total RNA was isolated using TRIzol (Invitrogen, Carlsbad, CA). For Northern blot analyses, 25 μg of total RNA was electrophoresed through a 1% agarose gel containing 2% formaldehyde and then transferred to a Hibond-N$^+$ nylon membrane (Amersham Biosciences Inc.). The filter was hybridized with each probe, which was labeled with [α-^{32}P]dCTP by using a random labeling kit (TaKaRa, Shiga, Japan). For RT-PCR, cDNA was synthesized using ReverTra Ace (Toyobo, Osaka, Japan), and polymerase chain reaction was performed using AmpliTaq Gold (Applied Biosystems, Foster City, CA). The primers used for amplification of the aP2 gene (a marker for adipocyte differentiation) were 5′-AAAATGTGTGATGCCTTTGTGGG-3′ and 5′-TCATGCCCTTTCATAAACTCTTGTGG-3′.

Results

Application of CoA-BAP System to Endocrine Disruptors. Reproductive abnormalities in wildlife can be associated with exposure to environmental pollutants capable of mimicking the action of natural hormones. Because the nuclear receptors of intrinsic hormone systems are likely to be targets of industrial chemicals, information on their ability to bind these chemicals is valuable for environmental risk assessment. To determine whether suspected endocrine disruptors can bind to members of the nuclear receptor family, we constructed assay systems for human nuclear receptors, including ERα/β, RARα/γ, TRα, VDR, RXRα/γ, PPARα/γ/δ, FXR, LXRα/β, and ERRα/γ, on the basis of the previously described CoA-BAP system (Kanayama et al., 2003). The cognate ligand for each nuclear receptor enhanced alkaline phosphatase activity in a dose-dependent manner (Fig. 1). In the ERR systems, 4-hydroxy tamoxifen-dependent dissociations between ERR and coactivator were observed, as reported previously (Coward et al., 2001; Tremblay et al., 2001).

Using these systems, we evaluated 40 suspected endocrine disruptors (Table 1) recognized by various organizations (e.g., World Health Organization and Ministry of the Environment in Japan). The effects of the tested chemicals on the interaction between nuclear receptors and TIF2 (Fig. 2) suggest that several compounds possess agonistic activities for multiple receptors simultaneously. Butyl benzyl phthalate, hexachlorocyclohexane, maneb, mancozeb, and alkylphenols were weakly agonistic for multiple receptors, including ER. One intriguing finding was that the effect of TBT on RXRα was as strong as that of its endogenous ligand, 9-*cis* retinoic acid (Fig. 3), and the agonist effect of TPT on PPARγ was as strong as that of its well known ligand, Rosi (Fig. 3). The EC_{50} values of TBT on RXRα (7.4×10^{-8} M) and TPT on PPARγ (9.5×10^{-8} M) were almost the same as those of 9-*cis* retinoic acid (4.3×10^{-8} M) and Rosi (1.1×10^{-7} M), respectively. Because triphenylmethane and triphenylethylene were not agonistic for RXRα and PPARγ, the tin moiety was important for activity (Fig. 3).

Organotin Compounds Potentiated Transactivation by RXR and PPARγ. The observations that organotin compounds enhanced the protein-protein interaction between the coactivator TIF2 and RXRα or PPARγ suggested that these compounds activate transcription via these receptors. To confirm the results we obtained from the CoA-BAP system, we performed a reporter gene assay in mammalian culture cells using an expression vector for (GAL4-DBD)-RXRα or (GAL4-DBD)-PPARγ and a reporter plasmid containing the luciferase gene along with GAL4 upstream activating sequence. Both TPT and TBT induced the transactivation function of RXRα or PPARγ in a dose-dependent manner (Fig. 4). The effectiveness of these organotin compounds was comparable with that of known ligands. In addition, dibutyltin chloride, a TBT metabolite in vivo, also activated reporter activity in the PPARγ system (data not shown).

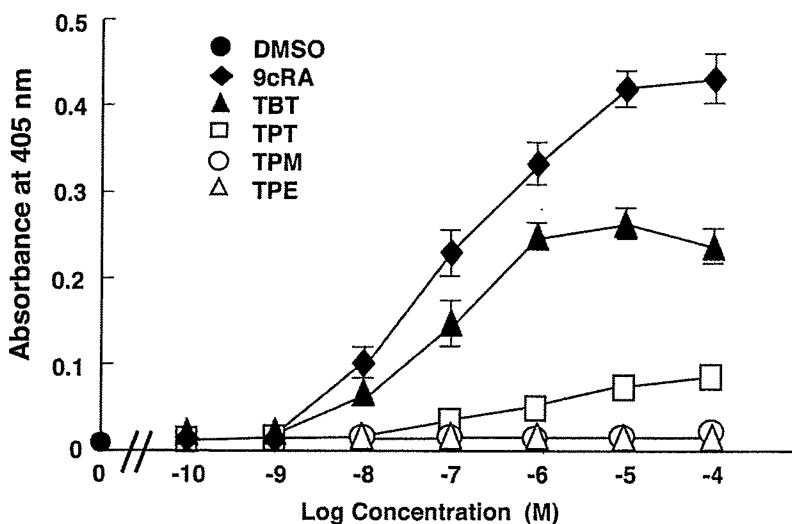
Induction and Promotion of Adipocyte Differentiation by Organotin Compounds in 3T3-L1 Cells. Recent studies indicate that PPARγ plays a central role in adipocyte gene expression and differentiation (Tontonoz et al., 1994). PPARγ is abundantly expressed in adipocytes, and its ligands induce the efficient conversion of fibroblastic cells to adipocytes, as measured by induction of adipocyte-specific genes and lipid accumulation (Lehmann et al., 1995). If or-

Fig. 2. Agonistic activities of suspected endocrine disruptors for various nuclear receptors. The effects of chemicals on the interaction between nuclear receptors and the coactivator TIF2 were assessed using the CoA-BAP system. The numbers in the far left column correspond to the chemicals listed in Table 1. The lowest effective concentrations of test chemicals were determined and compared with lowest effective concentration of cognate ligands shown in Fig. 1: red, ~1 to 10 times as much as cognate ligand; yellow, ~10 to 100; green, ~100 to 1000; gray, ~1000 to 10,000 times; and white, not detected. Triphenyltin (13) and tributyltin (14) showed strong activity on PPARγ and RXRα, respectively.

ganotin compounds can function as activators for PPARγ/RXR in vivo, these compounds probably induce adipocyte differentiation. To investigate this possibility, we treated 3T3-L1 cells with TPT or TBT in two types of differentiation medium, a complete differentiation medium that contained the inducers IBMX, Dex, insulin, and FBS and an incomplete differentiation medium that lacked IBMX and Dex. Although insulin is not always necessary for induction of differentiation, it efficiently enhances adipocyte development. Adipocyte differentiation was confirmed by staining with Oil Red O for lipid droplet accumulation. As expected, treatment of 3T3-L1 cells with either TPT or TBT in complete differentiation medium promoted adipocyte differentiation as well as did Rosi (Fig. 5, a–d). Even in incomplete differentiation medium, addition of organotin compounds induced adipocyte differentiation in contrast with the lack of induction after treatment with vehicle only (Fig. 5, e–h). Moreover, mRNA expression of the adipocyte differentiation marker aP2 was induced in a dose-dependent manner by addition of organotin compounds (Fig. 6a). PPARγ mRNA also was induced during the differentiation process (Fig. 6a), in agreement with the results of a previous study (Tontonoz et al., 1994). Induction of aP2 mRNA expression occurred late in adipogenesis (Fig. 6b), and organotin-treated cells demonstrated accumulation of triglyceride (Fig. 6c). Together, these data provide strong evidence that the organotin compounds TPT and TBT can function as inducers of adipocyte differentiation through PPARγ.

Discussion

Our study was designed to evaluate the effects of suspected endocrine disruptors on various nuclear receptors. The data show that several compounds have simultaneous effects on multiple nuclear receptors. In particular, organotin compounds (e.g., TBT and TPT) showed strong effects on RXR or PPARγ, at levels comparable with those of 9-*cis* retinoic acid, an endogenous RXR ligand, and rosiglitazone, a known agonist of PPARγ. In CoA-BAP systems, TBT showed strong effect on protein-protein interaction between RXRα and TIF2, but TPT showed slight effect (Fig. 3a). TPT showed strong effect on protein-protein interaction between PPARγ



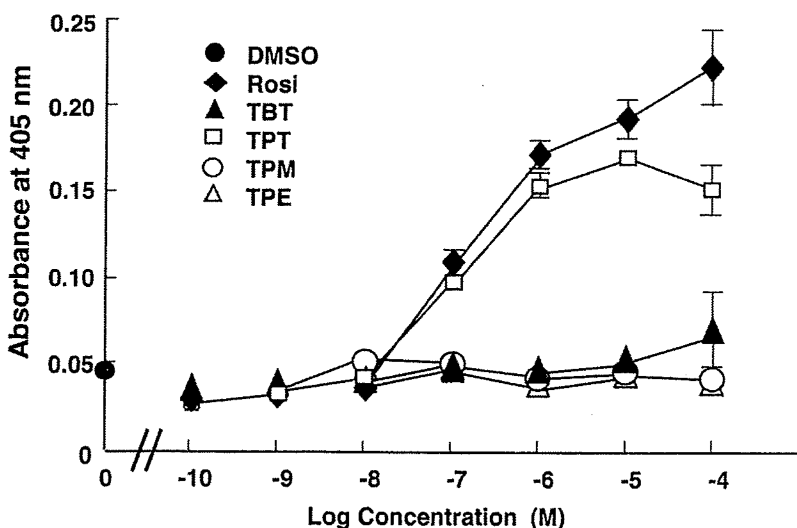


Fig. 3. Dose-response curves of the effects of organotin compounds on hRXRα and human PPARγ (hPPARγ) in the CoA-BAP system. A, TBT (▲) showed strong agonistic activity for hRXRα at as low a concentration as that of 9-*cis* retinoic acid (9cRA, ◆). B, TPT (□) showed strong agonistic activity to hPPARγ at as low a concentration as that of Rosi (◆). TPM (○) and TPE (△) did not show any agonistic activity. Activity of the vehicle control (dimethyl sulfoxide) only is shown by ●.

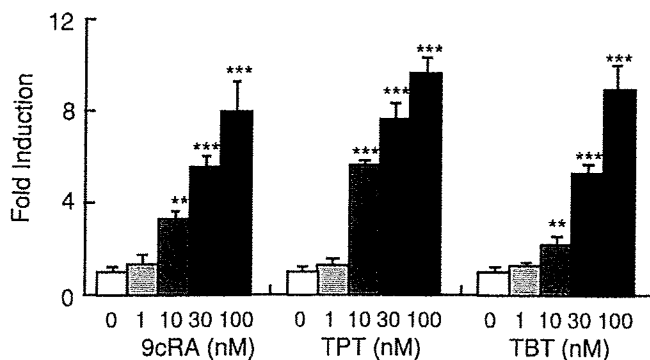
and TIF2, but TBT did not (Fig. 3b). On the contrary, when tested in the transactivation assay, both TBT and TPT activated not only RXRα but also PPARγ (Fig. 4). This discrepancy might reflect the diversity of coactivators. To date, many coactivators have been identified as nuclear receptor-interacting proteins. These coactivators are supposed to have cell- or tissue-specific functions in vivo (Smith and O'Malley, 2004). In addition, PPARγ reportedly changes its interaction partners depending on ligands (Kodera et al., 2000). We used only TIF2 in CoA-BAP system, whereas cells used for transactivation assays have many coactivators. The discrepancy of results from CoA-BAP systems and transactivation assays might be explained by this difference of coactivators. Because in vitro screening methods tend to produce false positive or false negative results like this, positive compounds should be further examined by other studies in a physiological context. Therefore, we examined the effects of organotin compounds on transcriptional regulation and adipogenesis, which is a famous physiological event related to PPARγ/RXR pathway.

Exposure of rats in utero to TBT induces a dramatic increase in the incidence of low-birth-weight fetuses because of maternal hypothyroidism (Adeeko et al., 2003). Furthermore, the RXR agonist bexarotene causes clinically significant hypothyroidism in patients with cutaneous T-cell lymphoma (Duvic et al., 2001), and experimental exposure of rats to LG100268 (a selective RXR agonist) induces the acute phase of hypothyroidism (Liu et al., 2002). The similarities between the toxicities of TBT and selective RXR agonists suggested to us that at least some of the toxic effects of organotin compounds are mediated by RXR.

Most of the toxic effects of organotin compounds on sexual development and reproductive function have been documented in mollusks (Matthiessen and Gibbs, 1998). In gastropods, TBT and TPT cause imposex (Morcillo and Porte, 1999), an irreversible syndrome in which male genital tracts (mainly a penis and a vas deferens) are imposed on female organisms (Smith, 1971). Although the physiological functions of organotin compounds have been studied extensively, the molecular target of organotin compounds had been unclear. To this end, we found that TPT and TBT were agonists for RXR and PPARγ. It has been thought that the sexual toxicity of organotin compounds results from increased androgen levels because of inhibition of the aromatase enzyme complex that catalyzes conversion of androgen to estrogen. This enzyme complex consists of microsomal CYP19 and the reduced form of the flavoprotein nicotinamide adenine dinucleotide phosphate reductase. TBT-induced imposex in neogastropods reportedly is mediated by inhibition of aromatase (Bettin et al., 1996), and TBT inhibits the catalytic activity of aromatase derived from transfected cells (Heidrich et al., 2001; Cooke, 2002). However, the effective concentrations of enzyme inhibition were relatively high (above 10^{-6} M). In this study, we found that TBT and TPT induced the transactivation function of RXRα and PPARγ at 10^{-8} M. It is reasonable that the effective concentration on gene expression was different from that on enzyme inhibition. In consistent with this, Nakanishi et al. (2004) demonstrated that 10^{-8} M TBT or TPT induced hCG or aromatase activity along with mRNA expression in placental cells (Nakanishi et al., 2002). In ovarian granulose cells, 20 ng/ml (about 6×10^{-8} M) TBT or TPT suppresses the $P450_{aroma}$ gene expression (Saitoh et al., 2001). We have to consider the toxicities of organotin compounds in distinguishing the low-dose effect from high-dose effect. Recently, we reported that RXR plays an important role in the development of gastropod imposex, by showing the cloning of RXR homolog from marine gastropod, binding of organotins to that receptor, and imposex induction by injection of RXR ligand 9-*cis* retinoic acid (Nishikawa et al., 2004). Gastropod imposex is known to be typically induced by very low concentrations of TBT and/or TPT (Bryan et al., 1986; Gibbs and Bryan, 1986; Horiguchi et al., 1997). Although it has been theorized that organotins increases androgen levels through inhibition of aromatase activity and/or a suppression of androgen excretion, the inhibitory concentration of organotins is not low enough for explaining imposex induction. The low-dose effects are likely to be mediated by receptors. However, the study of organotin effects in mammals is still important, because the compositions of nuclear receptor family members are very different between vertebrates and invertebrates (Escriva et al., 1997; Laudet, 1997). For example, there are no known homologs of steroid hormone receptors in the *Drosophila melanogaster* or *Caenorhabditis elegans* genomes, and the group members of TR, RAR, VDR, and PPAR seem to be late acquisitions dur-



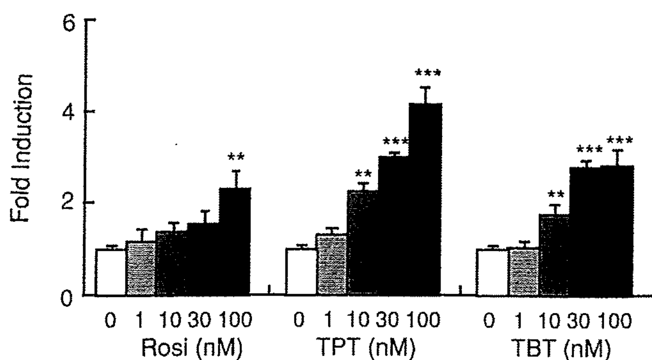


Fig. 4. Organotin compounds induce transcriptional activity through RXRα and PPARγ. Ligand-dependent transactivation of RXRα and PPARγ were detected as luciferase activity. a, F9 cells were cotransfected with a GAL4-DBD-hRXRα expression plasmid and a GAL4-responsive reporter plasmid. b, NIH-3T3 cells were cotransfected with a GAL4-DBD-mPPARγ1 expression plasmid and a GAL4-responsive reporter plasmid. The luciferase activities relative to the β-galactosidase activity are shown and represent the fold-stimulation compared with the activity of the vehicle-only control. Data shown are the means ± standard deviation of three independent experiments. **, $p < 0.01$; ***, $p < 0.001$ significantly different from vehicle controls.

ing the evolution of the superfamily. Therefore, we examined the effects of suspected endocrine disruptors on human nuclear receptor family members. As a result, PPARγ was identified as a new target molecule of organotin compounds in addition to RXR. This finding might introduce new insights in physiological functions of organotin compounds in mammals.

We were surprised to find that organotin compounds were high-affinity ligands for RXR and PPARγ. Until recently, it had been thought that among synthetic compounds, only hormone analogs could bind hormone receptors, because the relationships between hormones and their cognate receptors are very specific. However, some industrial chemicals do have unexpected effects on hormone receptors. Nuclear receptors are the likely targets, because their intrinsic ligands are fat-soluble, low-molecular-weight agents, as are the environmental pollutants. In fact, organotin compounds promote the adipocyte differentiation as agonists for PPARγ/

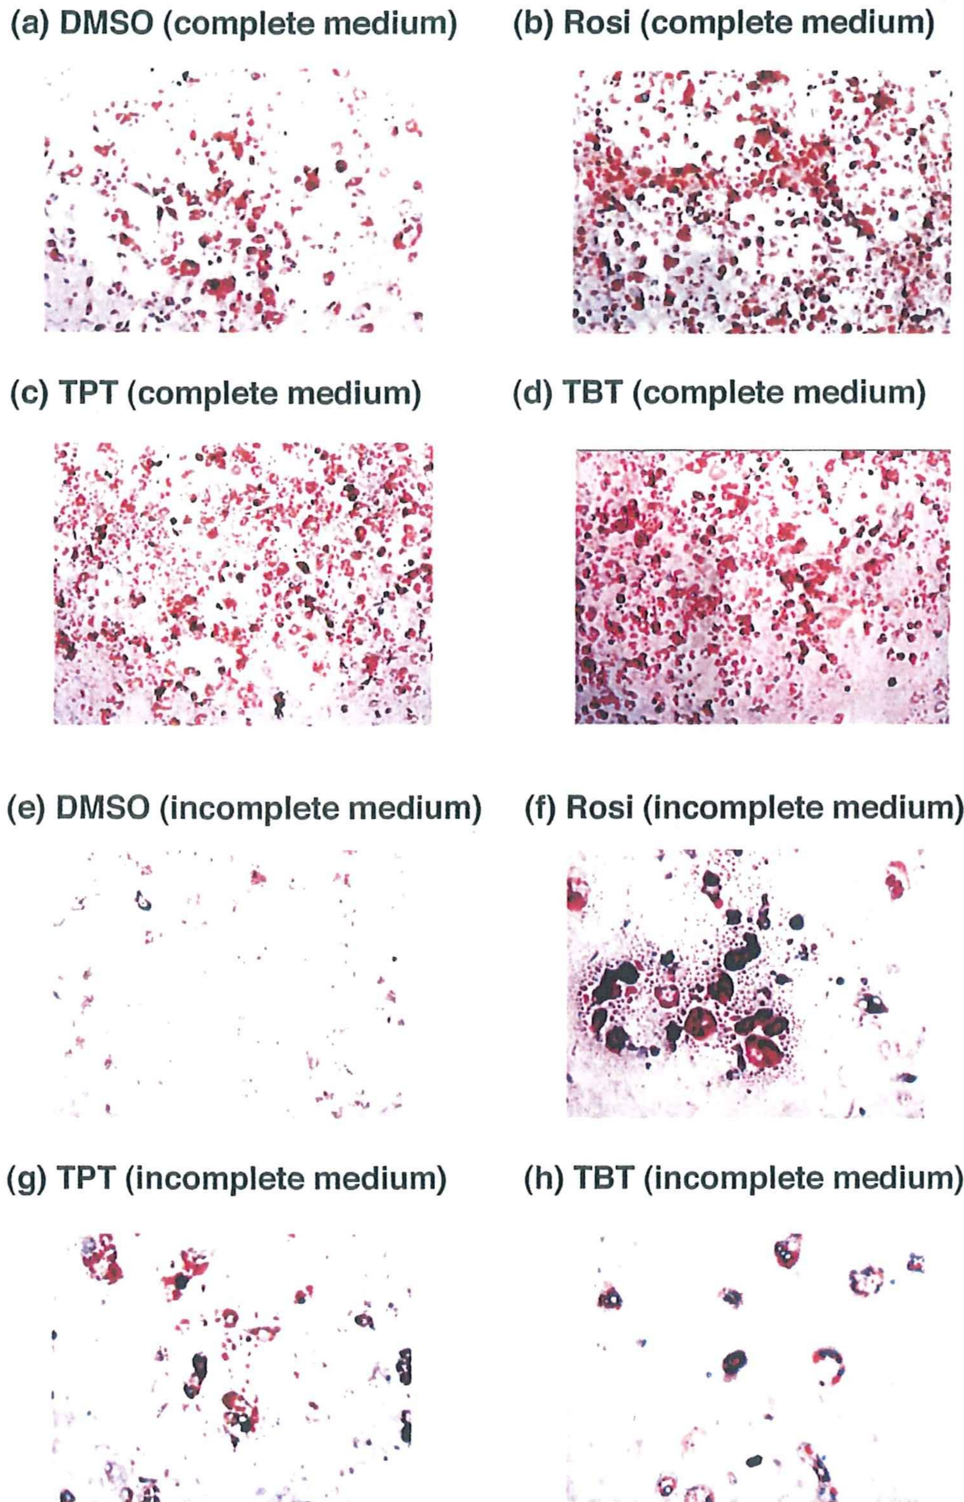

Fig. 5. Enhancement of lipid accumulation by organotin compounds. 3T3-L1 cells were maintained in DMEM containing 10% calf serum. One day after reaching confluence, the cells were treated for 60 h with vehicle only (a and e), 100 nM rosiglitazone (b and f), 100 nM TPT (c and g), or 100 nM TBT (d and h) in complete differentiation medium (a–d) or incomplete differentiation medium (e–h). The cells received fresh medium every 48 h. On the 10th day after induction of differentiation, the cells were fixed with paraformaldehyde and stained with Oil Red O.

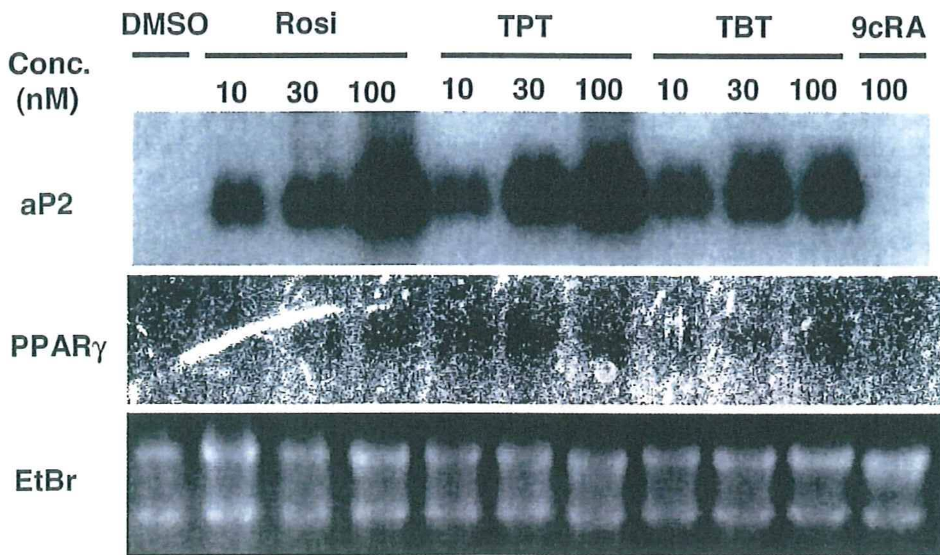

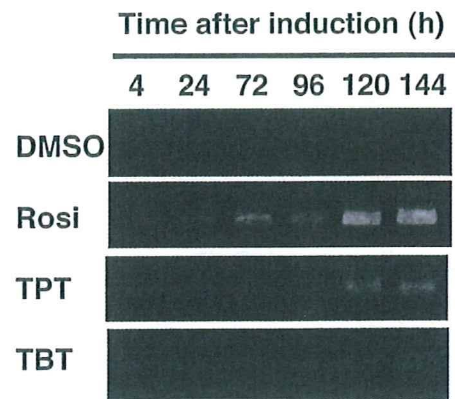

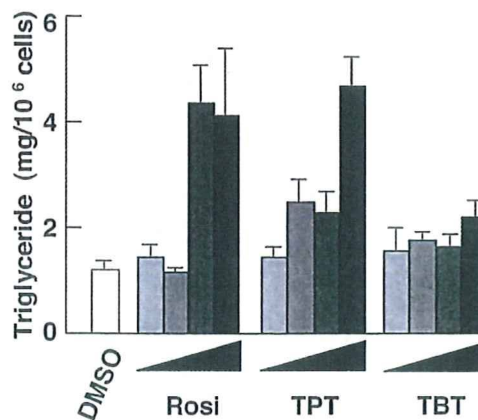

Fig. 6. Induction of adipocyte differentiation markers by organotin compounds. a, induction of adipocyte marker genes by organotin compounds in incomplete differentiation medium. 3T3-L1 cells were maintained in DMEM containing calf serum. One day after reaching confluence, the cells were treated with vehicle only, rosiglitazone (10–30 nM), TPT (10–30 nM), TBT (10–30 nM), or 9-*cis* retinoic acid (100 nM) in DMEM containing 10% FBS and 10 μg/ml insulin. Total RNA was isolated at 10 days after treatment, and mRNA expression of the aP2 and PPARγ genes was detected by Northern blot analysis. The ethidium bromide staining for ribosomal RNAs is shown as a control. b, time course of aP2 gene expression. 3T3-L1 cells were treated with vehicle only, rosiglitazone (100 nM), TPT (100 nM), or TBT (100 nM) in incomplete differentiation medium. The cells were harvested at the indicated time after treatment, and mRNA expression of the aP2 gene was analyzed by RT-PCR. c, lipid accumulation in differentiated 3T3-L1 cells. The cells were treated with 1, 10, 30, or 100 nM chemical. Ten days later, the amount of triglyceride was determined as described under *Materials and Methods*.

RXR. The ligands of PPARγ and RXR are expected for antidiabetic agents, but they have some side effects at the same time (Mukherjee et al., 1997; Yaki-Jarvinen, 2004). Although they may be good medicines when used under a doctor's control, wildlife are exposed to synthetic chemicals in uncontrolled manner. It is possible that TBT and TPT cause adverse health effects on the organisms by disturbing the endocrine process mediated by PPARγ/RXR.

Abstract

Eukaryotic DNA is packaged into chromatin, whose basic subunit is the nucleosome, which consists of DNA and a core histone octamer. Histone acetylation is important for the regulation of gene expression and is catalyzed by histone acetyltransferase (HAT). We observed the effects of suspected endocrine-disrupting chemicals (EDCs) on HAT activity. We showed that some organotin compounds – tributyltin (TBT) and triphenyltin (TPT) – enhanced HAT activity of core histones in a dose-dependent way and other EDCs did not affect HAT activity. Organotin compounds have various influences on physical function including the hormone and immune systems, embryogenesis, and development. Dibutyltin and diphenyltin, metabolites of TBT and TPT, respectively, also promoted HAT activity, but monobutyltin, monophenyltin, and inorganic tin had no effect. Further, TBT and TPT enhanced HAT activity when nucleosomal histones were used as substrates. These data indicate that the organotin compounds have unique effects on HATs independent of their EDC activities and suggest that the varied toxicities of the organotin compounds may be caused by aberrant gene expression following altered histone acetylation.

1. Introduction

Nuclear eukaryotic DNA is packaged into chromatin, which has a major impact on levels of gene transcription. The basic unit of chromatin is the nucleosome core particle, which consists of 146 bp of DNA wrapped around a histone octamer. This octamer con-

sists of two each of the core histones H2A, H2B, H3, and H4, all of which have a basic, unstructured amino terminal tail. These basic proteins are susceptible to a variety of posttranslational modifications, e.g., acetylation (Howe et al., 1999; Wu et al., 1986). One of the well-characterized modifications is acetylation of specific lysine residues, which is reversibly catalyzed by histone acetyltransferase (HAT) and histone deacetylase (HDAC).

The GCN5-related *N*-acetyltransferase family includes GCN5 and PCAF, which share a remarkable degree of homology throughout their sequences and are present in a multisubunit complex consisting of more than 20 distinct polypeptides (Ogryzko et al., 1998). GCN5 and PCAF are transcriptional coactivators with intrinsic HAT activity; they contribute to transcriptional activation by acetylating chromatin (Sterner and Berger, 2000). Disruption of *Gcn5* and *Pcaf* genes revealed that they play distinct but functionally overlapping roles during embryogenesis (Yamauchi et al., 2000). Other well-characterized coactivators possessing HAT activity are CBP and P300, which are ubiquitously expressed global transcriptional coactivators that have critical roles in a wide variety of cellular processes, including development (Giles et al., 1998; Giordano and Avantaggiati, 1999; Yao et al., 1998).

Recent studies have demonstrated that some environmental pollutants affect the hormonal system and produce adverse effects on animals and probably also humans (Colborn et al., 1996; Van der Kraak et al., 1992). These pollutants are referred to as endocrine-disrupting chemicals (EDCs). The major targets of EDCs are nuclear hormone receptors, which bind steroid hormones and regulate transcription of their target genes (Nishihara et al., 2000; Nishikawa et al., 1999). For ligand-dependent gene activation, nuclear hormone receptors require coactivators that link the basal transcriptional machinery with the hormone receptors (Chen, 2000). Recent studies have shown that the nuclear hormone receptor coactivators possess HAT activity and recruit two other types of HATs, CBP and PCAF (Chen et al., 1997; Spencer et al., 1997). Hormone-dependent gene activation mediated by nuclear receptors involves the mutual recruitment of at least three classes of HATs.

These observations raise the possibility that HATs may be the targets of EDCs, and we tested the effects of suspected EDCs on HAT activity. Interestingly tributyltin (TBT) and triphenyltin (TPT) enhanced HAT activity, but other EDCs did not. These organotin chemicals have been used in such applications as wood preservation and as antifouling agents in marine paints, and are ubiquitous in the environment. TBT and TPT have been found to induce imposex (the superimposition of male sex organs in female gastropods) in the rock shell *Thais clavigera* and are known EDCs in marine species (Horiguchi et al., 1997). These compounds are also reported to affect not only the hormone system but also embryogenesis in mammals (Harazono et al., 1998; Nakanishi et al., 2002). Organotins caused behavioral and neurological symptoms and pancreatic and hepatic toxicities in rodents (Brown et al., 1979; Merkord et al., 2001). In the immune system, at low doses TBT inhibits immature thymocyte proliferation, whereas at higher doses in particular TBT induces apoptotic cell death (Gennari et al., 2002). However, the biological mechanism of the effects of organotin compounds on marine species and mammals awaits further characterization. The present study showed that some organotin compounds enhanced HAT activity when both core and nucleosomal histones were used as substrates. These data suggest that the varied toxicities of the organotin compounds may be caused by aberrant gene expression following altered histone acetylation.

2. Materials and methods

2.1. Chemicals

All chemicals were dissolved in dimethyl sulfoxide (DMSO) (Wako Pure Chemicals, Osaka, Japan). Organotin and related chemicals tested are listed in Table 1.

2.2. Preparation of rat liver nuclear extracts and HAT fraction

All animal care and handling procedures were approved by the animal care and use committee of Osaka University. Rat liver nuclear extracts (RLNE) were prepared as described previously (Osada et al., 1995). For binding RLNE to Ni^{2+}-NTA agarose (Qiagen, Hilden, Germany), nuclei were suspended in a nuclear lysis buffer (10 mM HEPES, pH 7.6, 100 mM KCl, 10% glycerol, 3 mM $MgCl_2$, 5 mM 2-mercaptoethanol, and

[a] Core histones and 10 μM of chemicals were used for the HAT assay. Relative HAT activity shows mean HAT activities (±S.D.) relative to a control treated without chemical (three independent experiments). $^{*}P < 0.05$ and $^{**}P < 0.01$ compared to control.

1% protease inhibitor cocktail (Nacalai Tesque, Kyoto, Japan)), and 3 M KCl was added to a final concentration of 0.55 M. Nuclear lysate was gently mixed on ice for 30 min and centrifuged at 40,000 rpm in a Beckman 50.2 Ti rotor (Beckman, Fullerton, CA, USA) for 40 min at 4 °C. The RLNE was diluted by adding the same volume of nuclear lysis buffer without KCl and $MgCl_2$ and then incubating with preequilibrated Ni^{2+}-NTA agarose overnight at 4 °C on a rotating wheel. This suspension was poured into a column and the flowthrough was collected. The column was then washed with five column volumes of the nuclear lysis buffer without KCl and $MgCl_2$, and the retained proteins were eluted with a solution consisting of 20 mM imidazole (pH 7.5), 100 mM KCl, 10% glycerol, 5 mM 2-mercaptoethanol, and 1% protease inhibitor cocktail.

2.3. Western blotting and antibodies

Ten microliters of each fraction of column eluate was electrophoresed on an SDS-polyacrylamide gel, transferred to nitrocellulose, and detected with an ECL Western blotting analysis detection system (Amersham Biosciences, Piscataway, NJ, USA). Antibodies against P300, CBP, and GCN5 were obtained from Santa Cruz Biotech (Santa Cruz, CA, USA). Anti-PCAF antibody was kindly provided by Dr. Yoshihiro Nakatani (Harvard Medical School, Boston, MA, USA).

2.4. HAT assay

HAT assays were performed as follows: 1.5 μg core histones or nucleosome histones was incubated together with 5 μl of eluate from the Ni^{2+}-NTA agarose column, ^{3}H-labeled acetyl-CoA (0.25 μCi), and 1.2 μl of the test compound in 30 μl of HAT buffer (50 mM Tris–HCl, pH 8.0, 50 mM KCl, 5% glycerol, 0.1 mM EDTA, 1 mM dithiothreitol, 1 mM phenylmethylsulfonyl fluoride, 10 mM sodium butyrate) at 30 °C for 30 min. Histones were prepared as described previously (Owen-Hughes et al., 1999). After incubation, 15 μl of reaction mixture was transferred to a P81 phosphocellulose filter (Whatman, Brentford, UK) and allowed to air-dry. Filters were washed three times in wash buffer (50 mM $NaHCO_3$-$NaCO_3$, pH 9.2) and air-dried. The samples were counted in a scintillation counter (Beckman) for 10 min. The remaining 15 μl was subjected to SDS-polyacrylamide gel electrophoresis (PAGE). All gels were stained with Coomassie Brilliant blue to ensure loading of equivalent amounts of histone in each lane, then destained and flourographed.

2.5. Statistics

All results are expressed as means ± standard deviations (S.D.). Statistical analysis was performed by Dunnett's method.

3. Results

3.1. Partial purification of HAT complex from RLNE

To observe the effects of suspected EDCs on HAT activity, we used partly purified HAT complex from RLNE. Many HATs function as catalytic subunits in HAT complexes, and the specificity and the activity of HAT complexes are different from those of recombinant HATs. For example, recombinant GCN5 can acetylate core histones well, but it exhibits poor nucleosomal HAT activity (Balasubramanian et al., 2002; Grant et al., 1997). Recombinant SAS2 does not show HAT activity, but a complex including SAS2 can acetylate histones (Sutton et al., 2003). Grant and coworkers reported that some native HAT complexes in yeast bind to Ni^{2+}-NTA agarose (Grant et al., 1997). We wondered whether native mammalian HAT complexes bind to Ni^{2+}-NTA agarose. RLNE was incubated with Ni^{2+}-NTA agarose, and bound proteins were eluted with a buffer containing imidazole. Bound fraction included at least four HATs: GCN5, PCAF, P300, and CBP (Fig. 1).

3.2. Effect of TBT and TPT on core HAT activity

Nickel and curcumin (diferuloylmethane) were found to inhibit the acetylation of histones in vitro using recombinant histone acetyltransferase (Balasubramanyam et al., 2004; Broday et al., 2000), indicating that heavy metals and low molecular compounds may affect HAT activity. Suspected EDCs were screened for inhibition and activation of the HAT activity of partly purified HATs by the standard HAT assay procedure using core histone as substrate (Eberharter et al., 1998) and 20 chemicals in the list of chemicals suspected of having endocrine disrupting effects, as published by the Strategic Programs on Environmental Endocrine Disrupters '98, the Japan Environmental Agency (www.env.go.jp/en/pol/speed98/sp98.pdf). Tested 20 chemicals (benzophenone, octachlorostyrene, diethyl phthalate, butyl benzyl phthalate, diethylhexyl adipate, TPT, diethylhexyl phthalate, dicyclohexyl phthalate, di-*n*-butyl phthalate, TBT, 4-nonylphenol, *p*-octylphenol, bisphenol A, 2,4-dichlorophenol, 4-nitrotoluene, di-*n*-pentyl phthalate, dipropyl phthalate, pentachlorophenol, amitrole, and dihexyl phthalate) did not inhibit HAT activity. Interestingly TBT and TPT enhanced HAT activity but other chemicals did not (Fig. 2A and data not shown). HAT activity in the presence of various concentrations of TBT and TPT was assayed, and both chemicals demonstrated dose-dependent enhancement of HAT activity (Fig. 2A). TBT and TPT at both 1 and 10 μM promoted HAT activity but at 0.1 μM had little, if any, effect. Fluorography indicated that partly purified HATs from RLNE acetylated histones H2A, H3 and H4 and that these histones were more effectively acetylated in the presence of TBT or TPT (Fig. 2A, middle panel). A partly purified HAT fraction includes several kinds of HATs and HDACs, but TBT and TPT did not show HDAC inhibitory activity (data not shown). HDACs are classified into three groups, class I, II, and III. Assay reaction mixtures include butyrate, an inhibitor for class I and II HDACs (Ajamian et al., 2004). Further, TBT and TPT enhanced HAT activity in the presence of nicotinamide, an inhibitor for class III HDACs (Bitterman et al., 2002) (data not shown). These results also indicate that TBT and TPT do not inhibit HDAC activity.

We investigated the effects of organotin and related chemicals on HAT activity. TBT is metabolized to dibutyltin (DBT), monobutyltin (MBT), and inorganic tin; and TPT is metabolized to diphenyltin (DPT), monophenyltin (MPT), and inorganic tin (Horiguchi et al., 1997). The effects of these metabolites of the organotin compounds on HAT activity were also analyzed (Table 1). DBT and DPT enhanced HAT activity, but MBT, MPT, and $SnCl_4$ had no effect. DBT and DPT showed less enhancement of HAT activity than TPT and TBT, but tetrabutyltin did not affect HAT activity (Table 1). These results indicate that trialkyltin com-

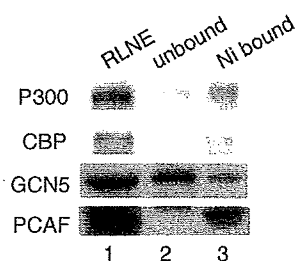

Fig. 1. Partial purification of HATs from RLNE. Western blots were performed with RLNE (lane 1), flow-through from a Ni^{2+}-NTA agarose column (unbound fraction, lane 2), and eluate from a Ni^{2+}-NTA agarose column (Ni-bound, lane 3) using antibodies against P300, CBP, GCN5, and PCAF.

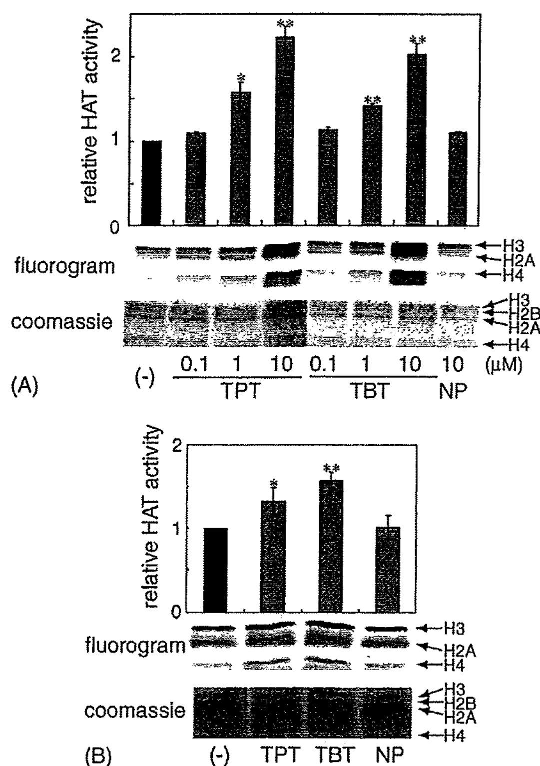

Fig. 2. Effect of TPT and TBT on HAT activity. (A) HAT assays with core histones as substrates and partly purified HAT fraction from RLNE as enzyme. The bar graph shows mean HAT activities (±S.D.) relative to a control treated without chemical (three independent experiments). 4-nonylphenol (NP) was used as a negative control. $^{*}P<0.05$ and $^{**}P<0.01$ compared to control. Products of HAT assays were separated by SDS-PAGE on 18% polyacrylamide gels to resolve the histones. The gels were stained with Coomassie Brilliant blue to visualize proteins (lower panel) and were then dried and visualized by fluorography (middle panel). (B) HAT assays in the absence or presence of chemicals (10 μM), TPT, TBT, and NP, using nucleosome histones as substrates were performed in triplicate as described in the legend to (A). A typical fluorogram from three independent experiments that showed similar results is shown.

pounds are more effective enhancers than other alkyltin compounds.

Next, we focused on the number of carbon alkyl chain in the trialkyltin compounds. Trimethyltin (TMT) did not affect HAT activity, and triethyltin (TET) was a poor promoter of HAT activity. Interestingly, tripropyltin was a more effective enhancer than the compounds containing one or more butyl or phenyl groups. The compounds containing carbon or silicon in place of tin were used to determine whether tin is essential for the promotion of HAT activity by organotin compounds. However, triphenylsilanol, triphenylmethane, and triphenylethylene did not affect HAT activity (Table 1).

3.3. *Effect of TBT and TPT on nucleosomal HAT activity*

Several transcription co-activators possess HAT activity, and the acetylation of nucleosomes associated with the promoter is correlated with transcriptional activation (Ikeda et al., 1999; Sterner and Berger, 2000; Utley et al., 1998). To investigate the effect of TPT and TBT on the nucleosomal HAT activity, we used nucleosomal histones as substrates instead of core histones (Fig. 2B). The partly purified HAT fraction from RLNE includes HAT activity for nucleosome histones, which was promoted by adding TPT and TBT to the reaction. This means that these compounds enhance the core HAT activity as well as the nucleosomal HAT activity.

4. Discussion

We demonstrated that HAT activity is enhanced by certain organotin compounds, including TPT and TBT. Here we found that: (1) trialkyltin compounds are more effective enhancers of HAT activity than mono- and dialkyltin compounds; (2) tin compounds with short alkyl chains showed no effect; and (3) the tin atom is important for the enhancement of HAT activity. On the basis of these results, it is likely that the acetyl CoA binding pocket (active site) or the substrate-binding site of HATs can tolerate a small compound, such as TMT or TET. These results suggest that both a carbon chain of a suitable length and a charge of tin are required for the regulating HAT activity. The crystal structure of HATs with acetyl CoA and/or histone has been determined (Dutnall et al., 1998; Rojas et al., 1999; Yan et al., 2000). Therefore, this information might be useful for analyzing the molecular mechanism of the enhancement of HAT activity by organotin compounds. However, we cannot rule out an alternative possibility that the organotin compounds affects histones. For example, organotin compounds may release histones from a inhibitor of acetyltransferase complex, which binds to histones and masks them from being HAT substrates

(Seo et al., 2001), or change the structure of the histone tails and making them better substrates. Zoroddu et al. propose that the binding of Ni (II) can produce a secondary structure with organized side-chain orientation in the amino terminal tail of histone H4 (Zoroddu et al., 2002). Some compounds including heavy metal(s) may affect histones. We used a partly purified HAT fraction so that the HAT complexes would be in their native form. To clarify the mechanism of HAT activity enhancement by organotin compounds, we are proceeding with identification of the specific HAT whose activity is activated by organotin compounds.

A cDNA microarray analysis revealed that expression of about 130 genes was induced by treatment of the ascidian *Ciona intestinalis* with TBT (Azumi et al., 2004). We previously reported that the level of the mRNA for aromatase/CYP19, which is essential for converting androgenic to estrogenic steroids, was increased by treatment of human choriocarcinoma JAR cells with TBT (Nakanishi et al., 2002). The mechanism of the induction of these mRNAs by TBT has not been elucidated yet. Aberrant HAT activity induced by TBT treatment might cause unusual expression of these genes.

HAT activity is required for the regulation of gene expression and histone acetylation has a fundamental biological role. Organotin compounds have various influences on physical function including the hormone and immune systems, embryogenesis, development, etc. In previous studies, reasonable butyltin concentrations were detected in human liver and blood (Kannan et al., 1999; Lo et al., 2003). Aberrant HAT activity in vivo induced by organotin compounds may cause abnormal development in human and wildlife. Our data indicate that the organotin compounds have unique effects on HATs independent of their EDC activities and suggest that the varied toxicities of the organotin compounds may be caused by aberrant gene expression following altered histone acetylation.

Acknowledgements

This research was supported in part by grants from the Japanese Ministry of Education, Science, Sports, and Culture and from the Takeda Science Foundation. We are grateful to Dr. Yoshihiro Nakatani (Harvard Medical School) for kindly providing anti-PCAF antibody. We also thank the staff of the Radioisotope Research Center, Osaka University.

Retinoid X receptor (RXR) is a nuclear receptor that plays important and multiple roles in mammalian development and homeostasis. We previously reported that, in human choriocarcinoma cells, tributyltin chloride and triphenyltin hydroxide, which are typical environmental contaminants and cause masculinization in female mollusks, are potent stimulators of human chorionic gonadotropin production and aromatase activity, which play key endocrine functions in maintaining pregnancy and fetal development. However, the molecular mechanism through which these compounds stimulate these endocrine functions remains unclear. Our current study shows that trialkyltin compounds, including tributyltin chloride and triphenyltin hydroxide, function as RXR agonists. Trialkyltins directly bind to the ligand-binding domain of RXR with high affinity and function as transcriptional activators. Unlike the natural RXR ligand, 9-*cis*-retinoic acid, the activity of trialkyltins is RXR specific and does not activate the retinoic acid receptor pathway. In addition, trialkyltins activate RXR to stimulate the expression of a luciferase reporter gene containing the human placental promoter I.1 sequence of aromatase, suggesting that trialkyltins stimulate human placental endocrine functions through RXR-dependent signaling pathways. Therefore, our results suggest that activation of RXR may be a novel mechanism by which trialkyltins alter human endocrine functions. (*Molecular Endocrinology* 19: 2502–2516, 2005)

THE RETINOID X receptors RXRα, RXRβ, and RXRγ, which are type II nuclear receptors, are thought to be key factors in several nuclear receptor signaling pathways. These molecules specifically bind 9-*cis*-retinoic acid (9cRA) and thus may be directly involved in the transduction of retinoid signals. In transfected cultured cells, as well as established cell lines, RXRs can act either as homodimers or heterodimeric partners of several other nuclear receptors, including retinoic acid receptors (RARα, -β, and -γ), thyroid hormone receptors (TRα and -β), vitamin D receptor (VDR), peroxisome proliferator-activated receptors (PPARα, -γ, and -δ), and a number of orphan receptors (1–3). Therefore, RXRs may be central to the modulation of several hormonal signals.

The placenta is a transient, but vital, organ for maintaining pregnancy in mammals. Its functions range from nutrient and gaseous exchange to hormone and growth factor production. Several observations suggest that RXRs play indispensable roles in placental development and physiology. In mice, RXRα transcripts are strongly expressed in the ectoplacental cone and, at later stages, in giant trophoblastic cells and the labyrinthine zone of the chorioallantoic placenta (4). RXR knock-out experiments in mice have revealed that RXRα and RXRβ are involved in the formation of the chorioallantoic placenta (5, 6). In particular, the inactivation of RXRα ligand-dependent transcriptional activation function 2, but not ligand-independent transcriptional activation function 1, prevents the formation of labyrinthine trophoblasts and leads to fetal death during the late fetal period or

shortly after birth (7). These placental abnormalities are similar to those found in the placentas of vitamin A-deficient rats (8). These observations suggest that the ligand-dependent transcriptional activation of RXRα is physiologically required for placentation in rodents.

RXRα mRNA and protein have been detected in human cytotrophoblasts and choriocarcinoma cells (9–11). Treatment of these cells with 9cRA and synthetic RXR-specific ligands increases the level of mRNA expression of steroidogenic enzymes, such as aromatase and human (h) chorionic gonadotropin (CG) (9, 10, 12–15). Estrogens and hCG are the principal hormones produced by the placenta during human pregnancy. These hormones are essential for several important events in the establishment and maintenance of pregnancy. Biosynthesis of estrogens requires the catalytic activity of an aromatase enzyme complex, which converts androgenic to estrogenic steroids (16). The human placenta exhibits a high level of aromatase activity and therefore regulates the balance of estrogens *in utero* (17). Altering aromatase function *in utero* can cause permanent effects in human embryos; the lack of placental aromatase causes female pseudohermaphroditism, as is seen in patients with aromatase deficiency (16, 18).

hCG is a luteotropic factor and the primary marker of pregnancy in humans. Stimulation by hCG governs not only progesterone production in the corpus luteum during the first trimester (19) but also testosterone production within the fetal testes (20). Given the pivotal functional roles of aromatase and hCG in sexual development and reproduction, the extant retinoid signals of RXR-mediated transcription in the placenta may greatly alter fetal development because of their disruption of these endocrine functions.

Organotin compounds have been used widely as biocides, agricultural fungicides, wood preservatives, disinfecting agents in circulating industrial cooling waters, and antifouling paints for marine vessels (21, 22). There are many reports of the biological effects of organotin compounds, which vary in their toxic effects to eukaryotes. One of the most notable toxicities in sexual development and reproduction is that of tributyltin (TBT)- and triphenyltin (TPT)-mediated endocrine disruption in some species of gastropods (23, 24). This phenomenon is known as "imposex," the superimposition of male genitalia on female. Therefore, these trialkyltin compounds are suspected to cause endocrine-disrupting effects in mammals, including humans. Human exposure to organotin compounds may result from the consumption of organotin-contaminated meat and fish products, occupational exposure during the manufacture and formulation of organotin compounds, or the application and removal of organotin-containing paints (25, 26). The possible exposure of humans to organotins has therefore aroused great concern about potential toxicities.

Previously, we reported that both tributyltin chloride (TBTCl) and triphenyltin hydroxide (TPTOH) enhance hCG secretion and aromatase activity in human choriocarcinoma cells. In addition, these compounds cause dose-related increases in the steady-state mRNA levels of both hCGβ and aromatase in human choriocarcinoma Jar cells after their exposure to nontoxic concentrations (27). These results suggest that these trialkyltin compounds are potent stimulators of human placental hCG production and aromatase activity *in vitro* and act as endocrine disruptors, the effects of which might alter local hCG and estrogen concentrations in pregnant women. However, the molecular mechanism underlying trialkyltin-induced alterations of human placental endocrine functions remains unclear. To extend our knowledge of the correlation between the structure of organotin compounds and their endocrine-disrupting effects, we assessed the effects of 17 tin compounds on hCG secretion, aromatase activity, and the mRNA levels of hCG and aromatase in Jar cells. We found that the effects of organotin compounds are related to both the number and length of their alkyl chains, suggesting that organotin compounds might interact with a target molecule in a fashion similar to that by which environmental estrogenic chemicals interact with estrogen receptors (28–34). Further, the promoter sequences of both human placental hCGβ and aromatase have several common half-site sequences (T/AGGTCA), of which nuclear receptor response elements typically are composed (13, 14). In addition, expression of both human placental hCG and aromatase is induced by specific RXR ligands (9, 10, 13, 14). In light of all of these results, we hypothesize that organotin compounds interact with RXRs to alter placental endocrine functions. Here we demonstrate that trialkyltin compounds bind to RXRs with high affinity and stimulate transcription through these receptors to alter endocrine functions in human choriocarcinoma cells.

RESULTS

Effects of Organotin Compounds on hCG Production and Aromatase Activity in Human Choriocarcinoma Cells

Previously, we reported that both TBTCl and TPTOH enhance hCG secretion and aromatase activity in human choriocarcinoma cells (27). To extend our knowledge of the correlation between the structures of organotin compounds and their endocrine-disrupting effects, we assessed the effects of 17 tin compounds (Fig. 1) on hCG secretion from, and aromatase activity in, Jar choriocarcinoma cells after their exposure to nontoxic concentrations of these compounds, which were determined from the results of [^{3}H]thymidine uptake assays (data not shown). The most active compounds were TBT or TPT derivatives (Fig. 2, Group III). Exposure to ≥ 10 nM of each of these trialkyltin compounds caused statistically significant increases in hCG production by Jar cells. Aromatase activity also

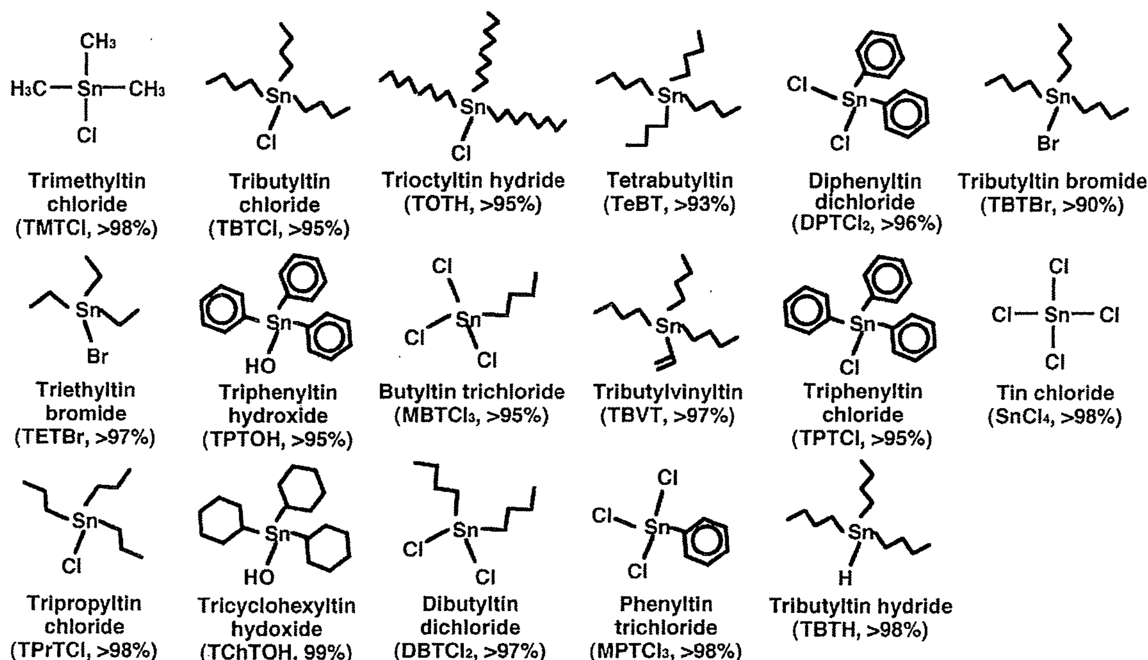

Fig. 1. Structures of the Tin Compounds Used in This Study
The abbreviation for, and purity of, each compound used are indicated in *parentheses*.

increased significantly as the concentrations of the TBT derivatives increased beyond 10 nM or those of the TPT derivatives increased in excess of 30 nM. Among the other trialkyltin compounds (Group I), tripropyltin chloride (TPrTCl) and tricyclohexyltin hydroxide (TChTOH) were active. Like the TBT and TPT compounds, TPrTCl stimulated both hCG production and aromatase activity, whereas TChTOH stimulated hCG production but not aromatase activity. Among the butyltin and phenyltin derivatives (Group II), neither of the mono-alkyltin compounds altered hCG production or aromatase activity. Dibutyltin dichloride ($DBTCl_2$) stimulated aromatase activity at 30 nM but failed to induce hCG production at any of the concentrations tested. In contrast, diphenyltin dichloride ($DPTCl_2$) stimulated hCG production at 30 nM but not aromatase activity at any tested concentration.

There were no significant differences in hCG production and aromatase activity among the TBT and TPT derivatives (Group III), suggesting that the ligand on the trialkyltin (as long as it is not an alkyl group) is relatively unimportant to the stimulation of these endocrine functions. However, the presence of a fourth alkyl group on the tin atom decreased the stimulus potency of the alkyltin compounds on hCG production and aromatase activity, because both tetrabutyltin (TeBT) and tributylvinyltin (TBVT) failed to stimulate these placental functions at doses less than 100 nM (Fig. 2, Group III). These results suggest that the potency of the effects induced by alkyltin compounds is related to both the number and length of the alkyl groups.

In addition, we investigated the tin compound-induced mRNA expression of hCGβ and aromatase at either the concentration that elicited the greatest response in each endocrine function or the maximal nontoxic concentration. The changes in hCGβ and aromatase mRNA expression were almost parallel to those in hCG secretion and aromatase activity (Fig. 3). These results indicate that the observed alkyltin-induced alterations in these placental functions are both caused by regulation at the mRNA level. Such overt correlation between the mRNA expression induced by alkyltin compounds and their structure led us to hypothesize that alkyltin compounds may interact with a nuclear receptor to alter placental endocrine functions; a similar mechanism has been demonstrated for environmental estrogenic chemicals that interact with estrogen receptors (28–34).

Interaction of Alkyltin Compounds with the Hormone-Binding Domain of RXRs

In human placental cells, both hCG production and aromatase activity are controlled by cAMP-dependent intracellular signal pathways. However, in our previous study, neither TBTCl nor TPTOH exerted any effect on cAMP production (27). After a literature search to identify a signaling pathway common to the mRNA expression of both hCG and aromatase, we arrived at the hypothesis that alkyltin compounds act as ligands of RXRs to activate the transcription of hCG and aromatase, because these placental factors are both induced by specific ligands of RXRs (9, 10, 13, 14). In

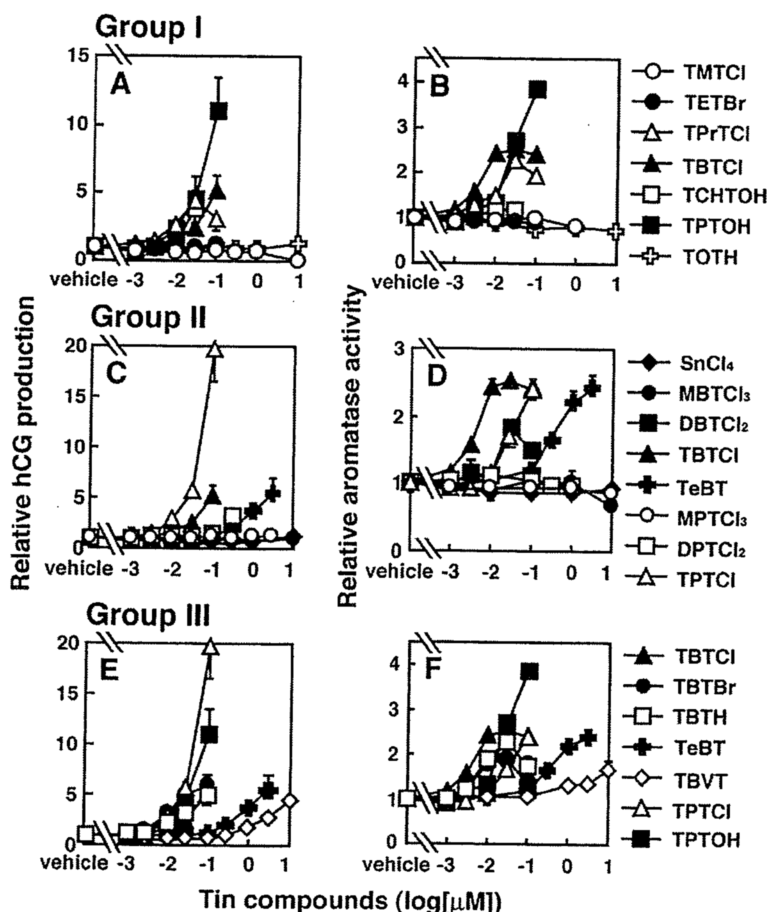

Fig. 2. Effects of Tin Compounds on hCG Secretion (A, C, and E) and Aromatase Activity (B, D, and F) in Jar Cells

Cells were treated with various nontoxic concentrations of tin compounds for 48 h. A nontoxic concentration of a tin compound was defined as a concentration at which the uptake of [^{3}H]thymidine was ≥ 80% that for the vehicle alone (data not shown). Results are expressed as mean ± 1 SD of triplicate cultures. Group I (A and B): comparison of different lengths of alkyl chains in trialkyltin compounds. Group II (C and D): comparison of different numbers of alkyl chains in butyltin and phenyltin compounds. Group III (E and F): comparison of different fourth function groups on the tin of TBT and TPT. The hCG production and aromatase activity in vehicle-only cells, calculated from all experiments, were 290.0 ± 85.3 mIU/well·24 h and 4.08 ± 0.91 pmol/well·4 h, respectively.

fact, we were able to confirm that a natural RXR ligand, 9cRA, and a synthetic RXR-specific ligand, LG100268, induced mRNA expression of both hCGβ and aromatase in Jar cells (Fig. 4).

Accordingly, we examined the dose-response effectiveness of TBTCl and TPTOH in stimulating RXR activity by using human choriocarcinoma JEG-3 cells cotransfected with a human RXRα expression plasmid and a luciferase (LUC) reporter plasmid containing an RXR response element (RXRE). RXR homodimers bind to direct repeat (DR)1 motifs (1–3). We constructed and used pTALDR1, which contains two DR1 sequences, as a reporter plasmid. Treatment with 1–100 nM 9cRA resulted in a 3- to 10-fold increase in LUC activity, whereas similar treatment with LG100268 led to a 3.3- to 4.5-fold increase (Fig. 5A). In addition, 100 nM 9cRA slightly stimulated the expression of LUC in JEG-3 cells transfected with a control plasmid, because JEG-3 cells express endogenous RXRα (10). Treatment of RXRα-transfected JEG-3 cells with 1–100 nM TBTCl stimulated LUC expression 1.5- to 9-fold, and exposing the cells to the same concentrations of TPTOH induced LUC expression 1.8- to 19-fold; these results suggest that low doses of these trialkyltin compounds activate RXR.

To identify the region of RXR involved in activation by alkyltin compounds, we used a chimeric receptor consisting of the DNA-binding domain of the yeast transcription factor GAL4 and the ligand-binding domain (LBD) of RXRα (GAL-RXR). Consistent with the results in Fig. 5A, the activity of the LUC reporter construct in JEG-3 cells cotransfected with the GAL-RXR chimeric receptor and the UAS-LUC reporter increased in a dose-dependent manner after incubation with not only 9cRA but also either TBTCl or TPTOH (Fig. 6). We then investigated the effect of the other tin compounds on activation of GAL-RXR chimeric receptors after exposure of the cells to nontoxic concentra-

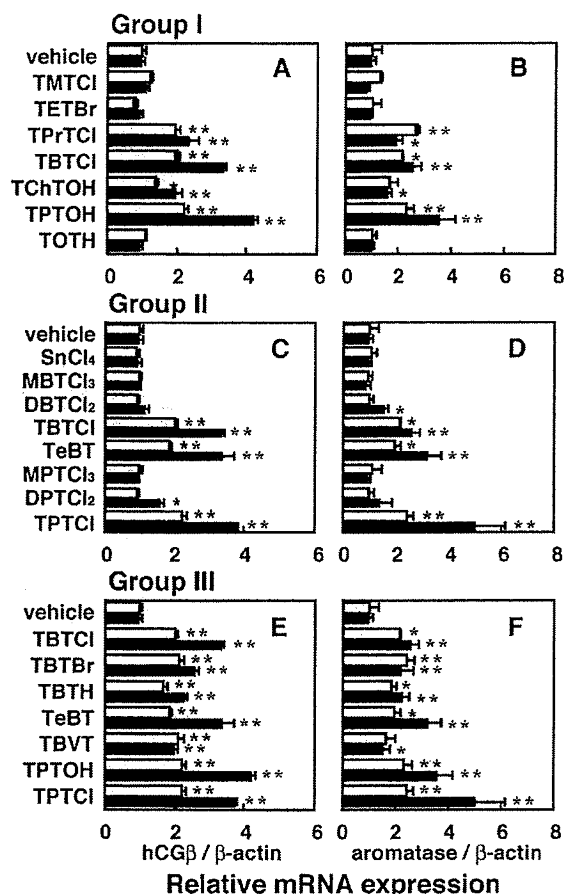

Fig. 3. Effects of Tin Compounds on the mRNA Expression of hCG β (A, C, and E) and Aromatase (B, D, and F) in Jar Cells

Total RNA isolated from Jar cells was treated with tin compounds for 24 h (*open bars*) and 48 h (*solid bars*). The concentrations of each compound were: 10 μM of TOTH, $SnCl_4$, $MBTCl_3$, and TBVT; 3 μM of $MPTCl_3$ and TeBT; 1 μM of 9cRA and TMTCl; 300 nM of $DPTCl_2$; 100 nM of TETBr, TBTCl, TPTOH, TPTCl, TBTBr, and TBTH; and 30 nM of TPrTCl, TChTOH, and $DBTCl_2$. The relative hCGβ and aromatase mRNA levels for each condition were determined by quantitative RT-PCR three times for each of the three independent cultures (see *Materials and Methods*). Results are expressed as mean ± 1 SD of three independent cultures. Groups I (A and B), II (C and D), and III (E and F) correspond to the groups described in the legend for Fig. 2. *, $P < 0.05$; **, $P < 0.01$; and ***, $P < 0.005$ *vs.* vehicle.

tions. TPrTCl, TeBT, and TBVT, as well as the TBT and TPT derivatives, activated transcription through GAL-RXR. TChTOH also activated transcription though GAL-RXR markedly, but the level of activation was only slight compared with that induced by the TBT and TPT derivatives. The level of GAL-RXR activation induced by these tin compounds was almost parallel to the increase in mRNA expression of hCGβ or aromatase in JEG-3 cells treated with these compounds.

RXR serves as a common heterodimerization partner for several receptors (1–3). In addition to RXR

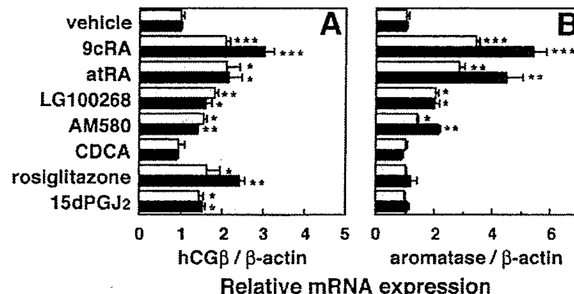

Fig. 4. Effects of Various Nuclear Receptor Agonists on the mRNA Expression of hCG β (A) and Aromatase (B) in Jar Cells

Total RNA isolated from Jar cells was treated with tin compounds for indicated time periods. The concentrations of each compound were: 10 μM of CDCA; 100 nM of 9cRA, atRA, rosiglitazone, or $15dPGJ_2$; and 100 nM of LG100268 or AM580. The relative hCGβ and aromatase mRNA levels for each condition were determined by quantitative RT-PCR three times for each of the three independent cultures (see *Materials and Methods*). Results are expressed as mean ± 1 SD of three independent cultures. *, $P < 0.05$; **, $P < 0.01$; and ***, $P < 0.005$ *vs.* vehicles.

homodimer, RXR-specific ligands can activate two types of complex. One type is the permissive heterodimers, such as PPAR-RXR (35–39) and farnesoid X-activated receptor (FXR)-RXR (40), which can be fully activated by a ligand of either RXR or its partner receptor and are activated synergistically in the presence of both ligands; the other is the conditionally permissive heterodimer RXR-RAR, which can be conditionally activated by RXR ligands only in the presence of an RAR agonist (38, 41). To identify the complexes involved in alkyltin-induced mRNA expression of both placental factors, we assessed the effects of the ligands of various RXR partners. The PPAR ligand 15-deoxy-$\Delta^{12,14}$-prostaglandin J_2 ($15dPGJ_2$) and the PPARγ-specific ligand rosiglitazone induced mRNA expression of hCGβ, but not aromatase, in Jar cells. Chenodeoxycholic acid (CDCA), an FXR agonist, failed to increase the mRNA expression of either placental factor. However, a natural RAR ligand, all-*trans*-retinoic acid (atRA), and a synthetic RARα-specific ligand, AM580, induced expression of the mRNA of both hCGβ and aromatase in human placental cells, as previously described (15). Furthermore, the natural RXR ligand 9cRA also can function as an RAR agonist to transactivate RXR-RAR heterodimer (1–3, 42). Accordingly, we examined whether typical trialkyltin compounds, which function as RXR agonists, can activate RXR-RAR transcription, as does 9cRA, by using LUC reporter plasmids containing an RAR response element (DR2 or DR5). Cells simultaneously transfected with human RXRα and RARβ expression vectors dramatically respond to atRA and 9cRA (Fig. 5B). Although TBTCl and TPTOH also stimulated the expression of LUC, the effectiveness of these organotin compounds was comparable to

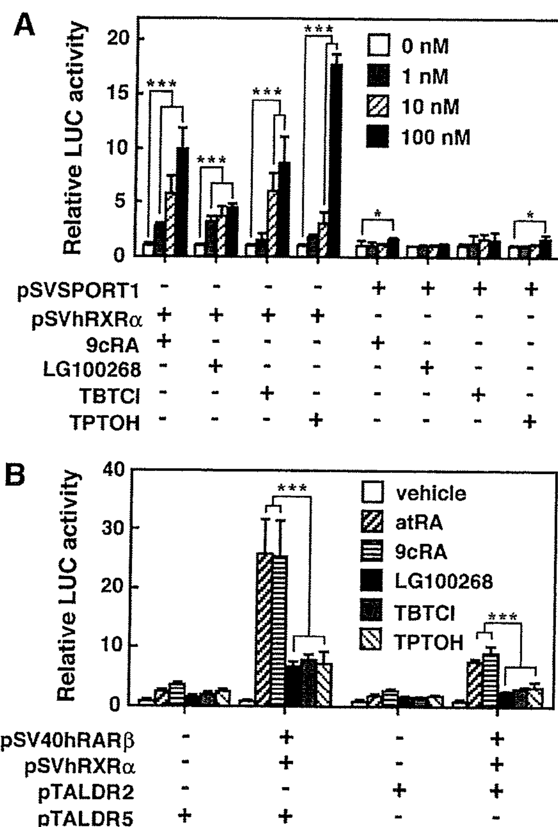

Fig. 5. Ability of TBTCl and TPTOH to Activate RXR and RAR

A, JEG-3 cells were cotransfected with 10 ng of either pSVhRXRα or pSVSPORT1 in addition to 0.1 μg pTALDR1 (see *Materials and Methods*) and then treated with various concentrations of 9cRA, LG100268, TBTCl, or TPTOH. B, JEG-3 cells were cotransfected with 10 ng each of pSVhRXRα and pSV40hRARβ in addition to 50 ng pTALDR2 or pTALDR5 and then treated with 100 nM of atRA, 9cRA, LG100268, TBTCl, or TPTOH. pRL-TK (2 ng) was cotransfected as the control for normalization (see *Materials and Methods*). The results are expressed as average fold activation ± 1 SD after normalization to *Renilla* LUC activity. *, $P < 0.05$; **, $P < 0.01$; and ***, $P < 0.005$.

that of LG100268, which does not transactivate RXR-RAR heterodimer (Fig. 5B). In addition, we examined the effect of TBTCl and TPTOH on activation of RARα, -β, and -γ by using chimeric receptors in which the GAL4 DNA binding domain was fused to the LBD of RARs (GAL-RARs) instead of RXRα. Neither alkyltin compound activated transcription through GAL-RARs (data not shown). These results suggest that the alkyltin compounds, which activate transcription of the reporter construct through GAL-RXR, interact with the LBD of RXR and transactivate RXR homodimer, but not RXR-RAR heterodimer, unlike 9cRA. Taken together, these results suggest that RXR homodimer may be involved in the alkyltin-induced mRNA expression of both placental factors, provided that the hCGβ induced also involves PPAR-RXR heterodimers.

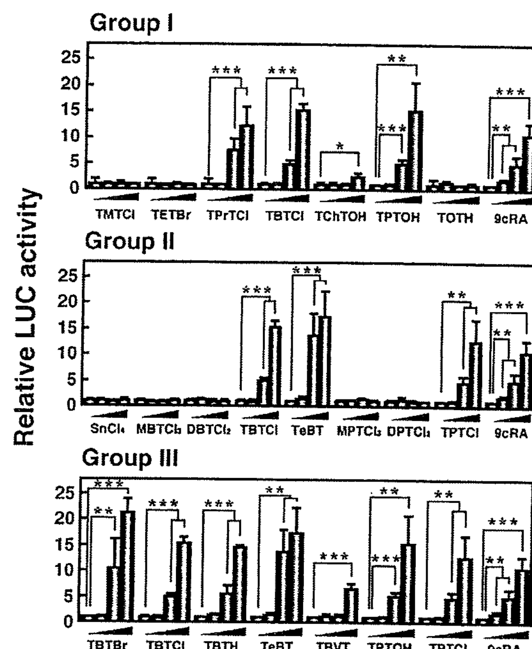

Fig. 6. Ability of Tin Compounds to Activate GAL-RXR

JEG-3 cells were cotransfected with 10 ng p4xUAS-tk-luc, 5 ng pBK-CMV-GAL4-hRXRα, and then treated with 9cRA or each of the tin compounds. The doses of each compound were: 0, 1, 10, or 100 nM of 9cRA, TETBr, TBTCl, TPTOH, TPTCl, TBTH, or TBTBr; 0, 0.1, 1, or 10 μM of TOTH, $SnCl_4$, $MBTCl_3$, or TBVT; 0, 1, 10, or 30 nM of TPrTCl, TChTOH, or $DBTCl_2$; 0, 0.1, 1, or 3 μM of $MPTCl_3$ or TeBT; 0, 10, 100, or 300 nM of $DPTCl_2$; and 0, 10, 100, or 1000 nM of TMTCl. pRL-TK (2 ng) was cotransfected as the control for normalization (see *Materials and Methods*). The results are expressed as average fold activation ± 1 SD after normalization to *Renilla* LUC activity. Groups I, II, and III correspond to the groups described in Fig. 2. *, $P < 0.05$; **, $P < 0.01$; and ***, $P < 0.005$.

Binding of Tin Compounds to RXR

To characterize the binding affinities of these tin compounds to RXR directly, we performed analyses of the saturation binding of [^{14}C]TPTOH and [^{3}H]9cRA to chimeric receptors, which consisted of glutathione *S*-transferase (GST) fused to the LBD of human RXRs (GST-RXRs). The binding of 9cRA to GST-RXRs was specific and saturative (Fig. 7). Scatchard analyses of the binding of [^{3}H]9cRA to GST-RXRα, -β, and -γ yielded dissociation constant (K_d) values of 11.7, 15.5, and 8.66 nM, respectively. These K_d values were similar to those previously reported (3, 42), suggesting that this system is useful for determining the binding affinity of alkyltin compounds to RXRs. Scatchard analyses of the binding of [^{14}C]TPTOH to RXRα, -β, and -γ yielded K_d values of 55.5, 241, and 95.3 nM, respectively (Fig. 7). Although the K_d values of TPTOH for RXRs were approximately 5- to 15-fold higher than those for 9cRA, our results indicate that TPTOH binds to the RXRs with high affinity in a saturable and specific manner.

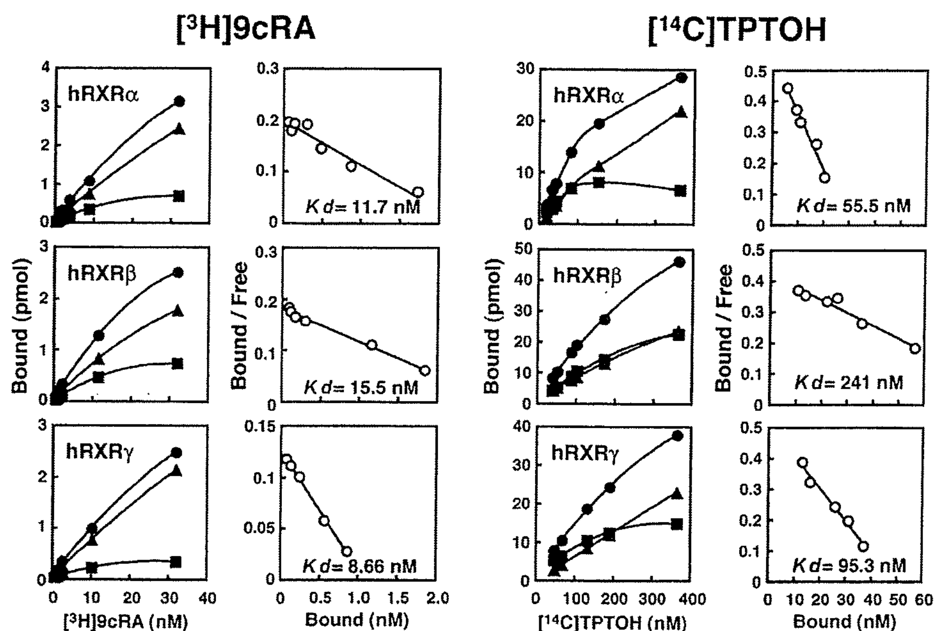

Fig. 7. Saturation Kinetics for the Binding of [^{3}H]9cRA and [^{14}C]TPTOH to hRXRα, -β, and -γ
Specific binding (*solid square*) is defined as total binding (*solid circle*) minus nonspecific binding (*solid triangle*). Scatchard analysis was performed on specific binding data (triplicates at each point) to yield the indicated dissociation constants (K_d value) for each receptor.

To further test which of the other tin compounds might bind to RXR as a ligand, we performed competitive ligand-binding assays. We measured the ability of [^{3}H]9cRA or [^{14}C]TPTOH to compete with the tin compounds for binding to GST-RXRα. The TBT and TPT derivatives all competed with [^{3}H]9cRA for binding to GST-RXRα in a concentration-dependent manner (Fig. 8). Consistent with the K_d value of TPTOH for RXRα, the IC_{50} value of TPTOH for binding [^{3}H]9cRA was approximately 5-fold higher than that of unlabeled 9cRA. The IC_{50} values of the other TBT and TPT derivatives for binding [^{3}H]9cRA were almost the same as that of TPTOH, demonstrating that these trialkyltin compounds bind directly to RXR. In contrast to the results of competitive assay for [^{3}H]9cRA, 9cRA failed to completely out compete [^{14}C]TPTOH for binding to GST-RXRα, whereas the TBT and TPT derivatives successfully competed for binding (Fig. 8B). The IC_{50} value of 9cRA for binding [^{14}C]TPTOH was more than 10-fold higher than those of TBTs and TPTs (Table 1). Further, TPrTCl bound to GST-RXRα as well as did the TBT and TPT derivatives, because its IC_{50} values for binding [^{3}H]9cRA and [^{14}C]TPTOH were almost the same as those of the TBT and TPT derivatives (Fig. 8 and Table 1). However, TChTOH, TeBT, and TBVT failed to compete with [^{3}H]9cRA for binding to GST-RXRα, despite their ability to activate RXRα. Although TChTOH out competed [^{14}C]TPTOH for binding to GST-RXRα, TeBT only slightly out competed [^{14}C]TPTOH, and TBVT failed to compete with [^{14}C]TPTOH for binding to GST-RXRα (Table 1). By contrast, triethyltin bromide (TETBr), which was unable to activate transcription through an RXR, bound weakly to GST-RXRα. The IC_{50} values of TETBr for binding [^{3}H]9cRA and [^{14}C]TPTOH were approximately 25- to 50-fold higher than those of the TBT and TPT derivatives (Table 1). The remaining tin compounds (trimethyltin chloride, TMTCl; trioctyltin hydride, TOTH; butyltin trichloride, $MBTCl_3$; phenyltin trichloride, $MPTCl_3$; $DBTCl_2$; $DPTCl_2$; and $SnCl_4$) did not compete successfully with either [^{3}H]9cRA or [^{14}C]TPTOH for binding to GST-RXRα, suggesting that they were unable to bind to RXRs.

Trialkyltin Compounds Stimulate the Expression of an LUC Construct Containing the Human Placental I.1 Sequence of Aromatase via Activation of RXRα

To determine whether trialkyltin compounds, which bind to and activate RXRs, induce aromatase expression in the human placenta via ligand-dependent activation of RXRs, we assessed the dose-response effectiveness of TBTCl and TPTOH by using JEG-3 cells cotransfected with a human RXRα expression plasmid and a LUC reporter plasmid containing the promoter sequence (−2295 to +107 bp) of exon I.1, which is the major promoter of human placental aromatase (Fig. 9A; and Refs. 16, 43, and 44). As expected, LG100268 stimulated the expression of LUC by 2.4- to 3.5-fold. These results suggest that the aromatase promoter is regulated by ligand-bound RXR (13). In addition, TBTCl and TPTOH stimulated the expression of LUC in
