
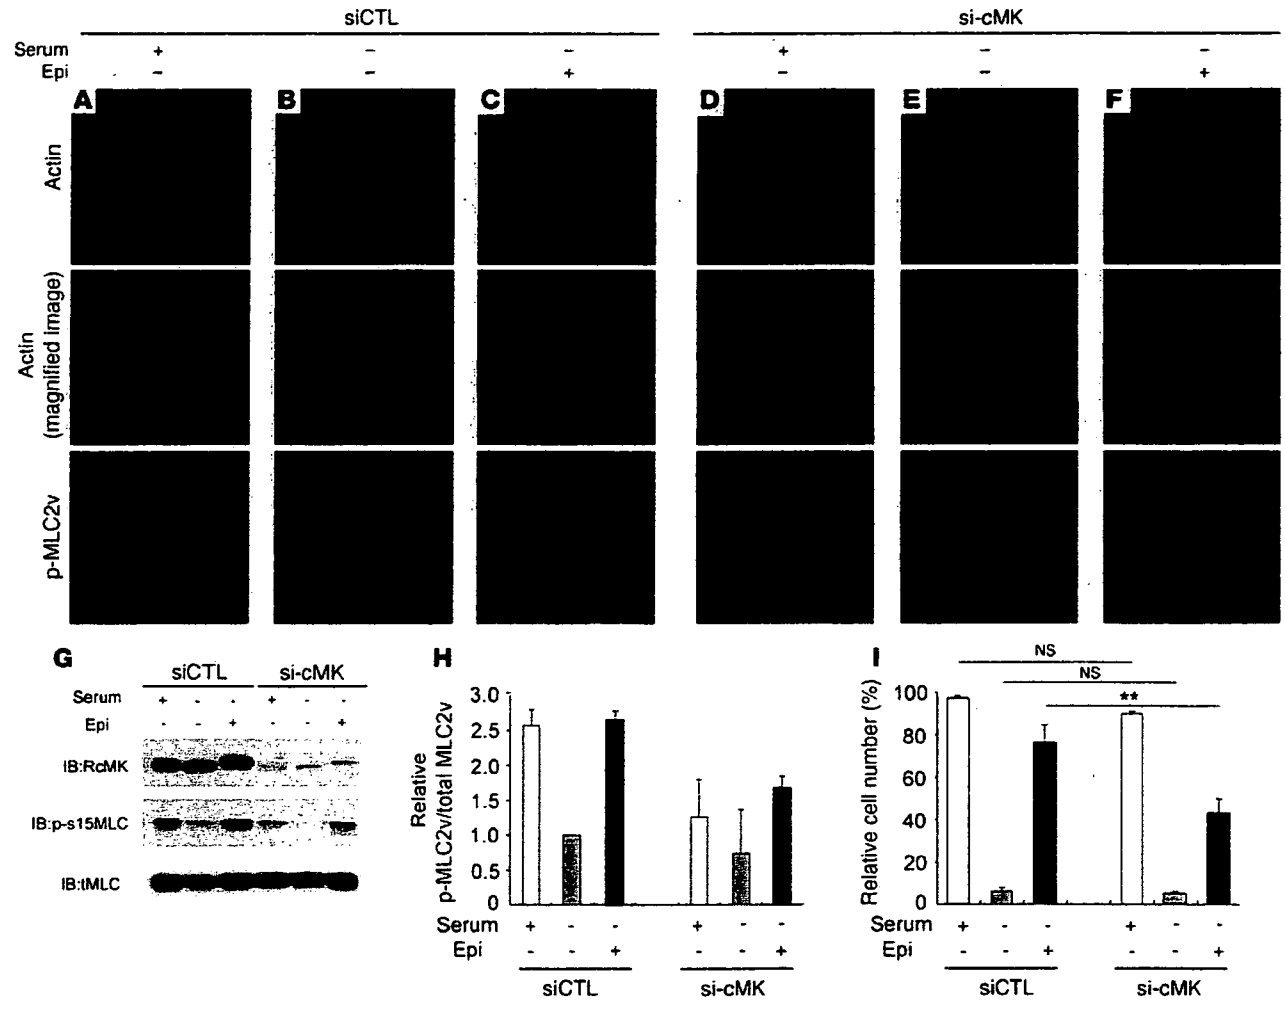

Figure 4

Cardiac-MLCK regulates the initiation of sarcomere assembly in cultured cardiomyocytes through MLC2v phosphorylation. Original magnification, ×1,000 (upper and lower panels); ×2,000 (middle panels). (**A–F**) Cardiomyocytes were transfected with control siRNA (**A–C**) or si-cMK (**D–F**). Middle panels show higher magnification of boxed regions in top panels. In serum-containing conditions, si-cMK–transfected cardiomyocytes showed reduced levels of MLC2v phosphorylation (**D**) compared with control siRNA–transfected cardiomyocytes (**A**), although both exhibited regularly organized sarcomere structures. Actin staining in cardiomyocytes cultured in serum-free conditions revealed a punctuated pattern in the sarcomeres (**B** and **E**); moreover, the degree of MLC2v phosphorylation was reduced in the si-cMK–transfected cardiomyocytes compared with the control siRNA–transfected cardiomyocytes. Stimulation with 2 μM epinephrine provoked upregulation of MLC2v phosphorylation and sarcomere reassembly in control siRNA–transfected cardiomyocytes (**C**), but not in si-cMK–transfected cardiomyocytes (**F**). (**G**) We confirmed the levels of MLC2v phosphorylation shown in **A–F** using immunoblot analysis. (**H**) Quantitation of the levels of phosphorylated MLC2v shown in **G**. Values are mean ± SEM. (**I**) Percentage of the cells with organized sarcomeres. There was no significant difference between the populations of cardiomyocytes transfected with control siRNA and si-cMK under either serum-containing or serum-free conditions. The percentage of the cells with organized sarcomeres was significantly higher for the control siRNA–transfected cardiomyocytes than for the si-cMK–transfected cardiomyocytes. Values are mean ± SEM. p-MLC2v, phosphorylated MLC2v. $^{**}P < 0.001$.

MOs effectively deleted the targeted exons, inducing comparable ventral swelling phenotypes (Figure 6, D–F). The finding that 4 different MOs produced similar results suggests that the cardiac phenotypes resulted from a loss of the kinase activity of z-cardiac-MLCK. To evaluate the cardiac phenotype of the z-cMKaugMO morphants in detail, we examined the SAG4A zebrafish strain, which specifically expresses GFP in the cardiac ventricle (14). After injecting z-cMKaugMO into SAG4A embryos, cardiac motion at 72 hpf was imaged with a high-sensitivity digital camera attached to a fluorescence stereomicroscope (Figure 6G and Supplemental Movies 1 and 2; supplemental material available online with this article; doi:10.1172/JCI30804DS1). Recordings were converted to motion mode (M-mode) images using our original software (Figure 6H). From these images, we determined the end-diastolic dimension (Dd), end-systolic dimension (Ds), and fractional shortening (FS) of the cardiac ventricle. These data are summarized in Table 2, and the results indicate that the cardiac dimensions of the z-cMKaugMO morphants were significantly larger than those of control zebrafish embryos (Dd, 79.6 ± 3.7 versus 117.0 ± 10.4 μm; Ds, 50.3 ± 6.5 versus 76.0 ± 7.0 μm; $P < 0.0001$ for both com-

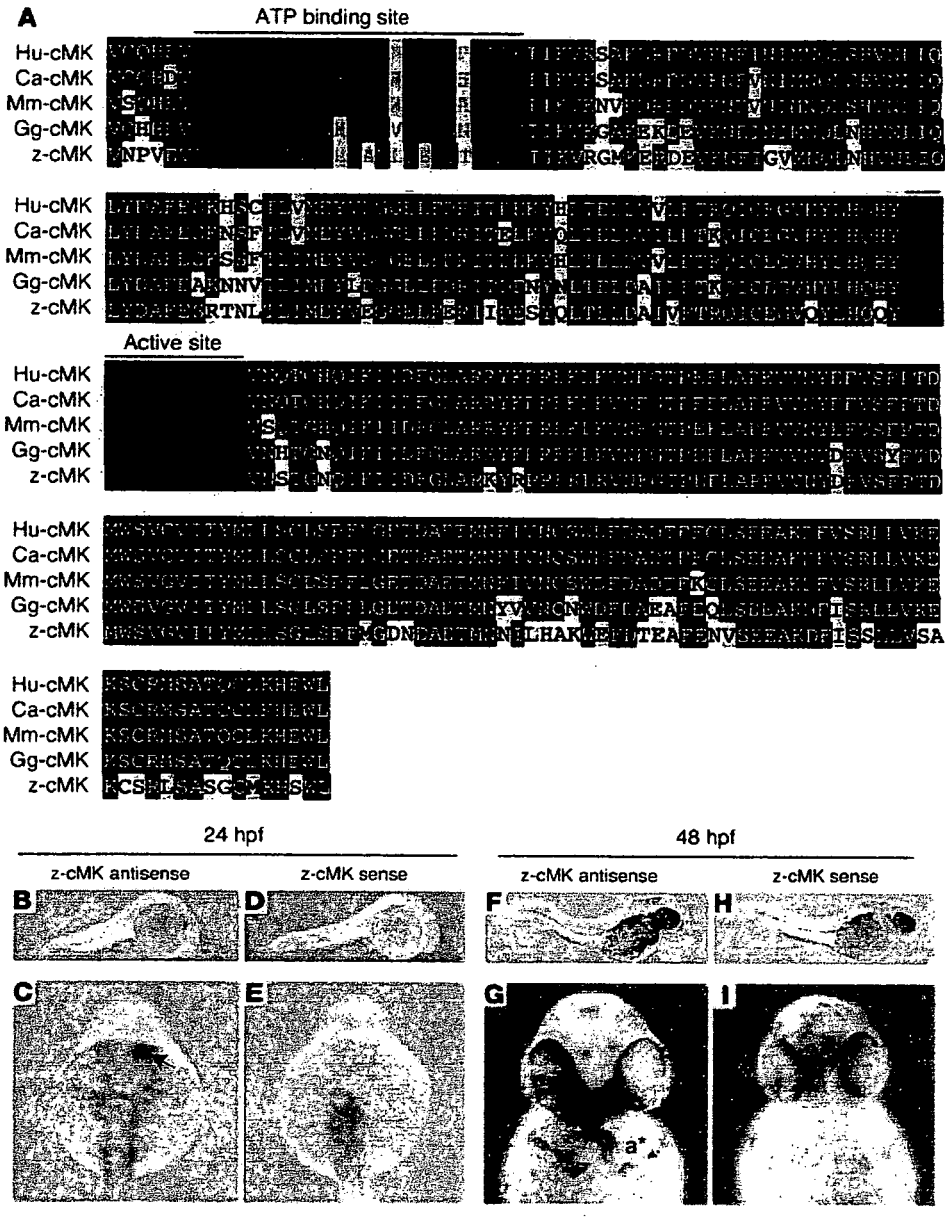

Figure 5
Cardiac-MLCK is highly conserved in several vertebrates, including zebrafish. (**A**) Cardiac-MLCK is evolutionarily conserved in vertebrates, including humans (Hu), dogs (Ca), mice (Mm), chickens (Gg), and zebrafish (z), with the highest degree of homology in the C-terminal portion of the serine/threonine kinase domain. Black backgrounds indicate identical amino acids. Amino acids in the ATP-binding region are shown in blue; those in the kinase active site are shown in red. (**B–I**) Whole-mount in situ hybridizations depict the expression of z–cardiac-MLCK (z-cMK) in zebrafish embryos hybridized with z–cardiac-MLCK–specific antisense probe (**B**, **C**, **F**, and **G**) or z–cardiac-MLCK sense probe (**D**, **E**, **H**, and **I**). At 24 hpf, z–cardiac-MLCK was expressed in heart precursor cells (arrow). At 48 hpf, z–cardiac-MLCK was selectively expressed in the heart (asterisks denote atrium [a] and ventricle [v]).

parisons). We did not, however, observe a significant difference in cardiac contractility as assessed by the FS (36.9% ± 7.1% versus 34.9% ± 4.1%; NS), likely because of a compensatory upregulation of inotropy. In support of this hypothesis, we observed that the heart rate was significantly higher in the z-cMKaugMO morphants (184 ± 14.5 versus 216 ± 24.7 bpm; $P = 0.0017$). At 5–6 days after fertilization, the z-cMKaugMO morphants developed systemic edema and died of circulatory disturbances. Histopathologic analysis demonstrated that the ventral swelling in the z-cMKaugMO morphants reflected pericardial edema. Although the cardiac atria were almost normal, the ventricular walls of the morphants were thinner than those of control zebrafish embryos (Figure 7, A–D). Transmission electron microscopy revealed that only a few poorly differentiated sarcomere structures were present in the ventricles of the z-cMKaugMO morphants (Figure 7, G–J); no other apparent abnormalities were detected in the atrial sarcomeres (Figure 7, E and F). These data suggest that cardiac-MLCK is required for sarcomere formation in the developing heart.

Cardiac-MLCK is upregulated during myofibrillogenesis and in mammalian models of heart failure. Sarcomere organization in cardiomyocytes in vivo is supposed to occur during myofibrillogenesis. In the rat heart, the mRNA and protein levels of cardiac-MLCK were upregulated from 1 week after birth through adulthood (Figure 8, A and B). The expression of cardiac-MLCK mRNA was also analyzed in mammalian models of heart failure. Myocardial infarctions (MIs) were produced in Wistar rats by permanently ligating the left anterior descending artery. At 4 weeks after the onset of MI, heart failure developed. The hemodynamic and echocardiographic parameters of the MI and sham-operated rats are summarized in Table 3. In MI rats, the LV end-diastolic pressure and LVDd were significantly higher than in sham-operated rats (LV end-diastolic pressure, 20.5 ± 8.2 versus 3.2 ± 1.0 mmHg; $P < 0.01$;

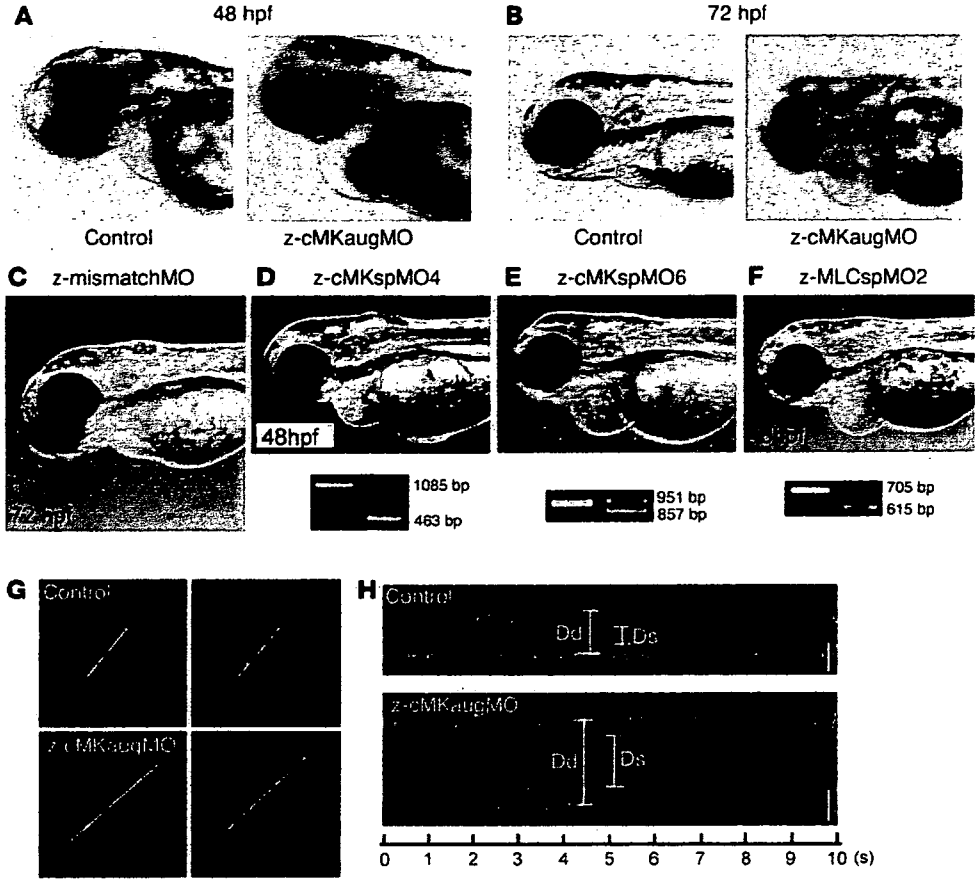

Figure 6

Suppression of z–cardiac-MLCK expression induced dilatation of the cardiac ventricle in zebrafish embryos. (**A** and **B**) Control mock-injected zebrafish embryos and zebrafish embryos injected with z-cMKaugMO produced the phenotype of ventral swelling at 48 hpf (**A**) and 72 hpf (**B**). (**C**) Zebrafish embryos injected with MOs with 5-base mismatch to z-cMKaugMO (z-mismatchMO) showed phenotypes comparable to those of controls. (**D** and **E**) Injection of specific MOs designed to interfere with the splicing of z–cardiac-MLCK exon 4 (z-cMKspMO4; **D**) or exon 6 (z-cMKspMO6; **E**) or with the splicing of z-MLC2v exon 2 (z-MLCspMO2; **F**), which coded for the phosphorylatable serine residue, also induced the phenotype of ventral swelling. RT-PCR products amplified from cDNA produced from the morphants were shorter than those obtained from control embryos due to the removal of the targeted exons. (**G**) Cardiac motion in the control embryos and z-cMKaugMO morphants. Shown are end-diastolic (left) and end-systolic (right) phases of the cardiac ventricular cycle in a control embryo and z-cMKaugMO morphant. (**H**) Representative M-mode images of both control embryo and z-cMKaugMO morphant hearts. Scale bars: 50 μm. Original magnification, ×20 (**A–F**); ×100 (**G**).

LVDd, 9.8 ± 0.3 versus 6.8 ± 0.5 mm; $P < 0.01$), whereas the maximum LV peak rate of change in pressure during isovolumic contraction (Max dP/dt) and FS were significantly lower than in sham-operated rats (Max dP/dt, 5,845 ± 1,156 versus 9,440 ± 644 mmHg/s; $P < 0.01$; FS, 12.0 ± 3.1 versus 44.0 ± 7.8%; $P < 0.01$). In MI rats, *MYLK3* expression was significantly upregulated compared with that in the sham-operated rats (relative cardiac-MLCK mRNA expression, 1.46 ± 0.42 versus 1.00 ± 0.15; $P < 0.05$; Figure 8C). Furthermore, the relative mRNA expression level of cardiac-MLCK was significantly correlated with that of ANP ($r = 0.778$, $P < 0.005$; Figure 8D). Upregulation of cardiac-MLCK expression in the infantile heart suggests cardiac-MLCK participates in myofibrillogenesis. Additionally, upregulation of cardiac-MLCK mRNA levels in mammalian models of heart failure confirmed the results obtained with the microarray analysis of human failing myocardia.

Discussion

In this study, we performed microarray analysis of human failing myocardia to identify new genes involved in the pathophysiology of CHF. By comparing mRNA expression analysis with the clinical parameters of the patients, we identified what we believe to be a novel candidate gene, *MYLK3* (encoding cardiac-MLCK), that had not been isolated in previous microarray studies of heart failure (15). Upregulation of *MYLK3* transcription in failing myocardia was confirmed in mammalian models of heart failure, such as MI rats. In this experiment, mRNA expression of cardiac-MLCK was significantly upregulated in MI rats with heart failure, and the relative expression profile was well correlated with that of ANP, a representative marker of CHF.

MLCK family members in muscle are sarcomeric protein kinases that phosphorylate a serine residue near the amino terminus of the myosin regulatory light chain. In cardiac muscle, phosphorylation of MLC2v led to sarcomere organization, an event that represents cardiac hypertrophy in cultured neonatal rat cardiomyocytes (13). skMLCK is thought to be the predominant kinase that acts on MLC2v, and a gradient of MLC2v phosphorylation in the cardiac wall from endocardium to epicardium is responsible for the generation of cardiac torsion (9). A recent study using skMLCK-deficient mice, however, revealed that removing skMLCK did not result in a cardiac phenotype (10). Furthermore, in the current study and previous studies, skMLCK expression was not detected in the heart by either Western blotting or RT-PCR (16), suggesting the existence of an as-yet unknown kinase that phosphorylates MLC2v in cardiac muscle.

We identified cardiac-MLCK, which serves as a specific kinase for MLC2v in cardiac muscle. In cultured cardiomyocytes, cardiac-MLCK regulates sarcomere assembly through the phosphorylation of MLC2v. When isolated cardiomyocytes were cultured under serum-free conditions, established sarcomere structures were disrupted. Overexpression of recombinant cardiac-MLCK and exogenous stimulation by epinephrine promoted sarcomere

Table 2
Cardiac physiological characteristics of control and morphant zebrafish embryos

	Control	Morphant	*P*
Dd (μm)	79.6 ± 3.7	117 ± 10.4	<0.0001
Ds (μm)	50.3 ± 6.5	76.0 ± 7.0	<0.0001
FS (%)	36.9 ± 7.1	34.9 ± 4.1	NS
HR (bpm)	184 ± 14.5	216 ± 24.7	0.0017

Values are mean ± SEM. n = 12 per group. HR, heart rate.

reassembly through MLC2v phosphorylation. Similar findings have previously been reported using recombinant constitutively active skMLCK (13). We further elucidated the physiologic roles of endogenous cardiac-MLCK using siRNAs. Decreases in MLC2v phosphorylation following the introduction of si-cMK significantly impaired epinephrine-induced sarcomere reassembly. Additionally, specific knockdown of cardiac-MLCK did not affect to the expression of other sarcomere-related proteins such as troponin T, desmin, and α-actinin. These proteins are thought to have important roles in sarcomere and myofibril formation (17–19). Thus, in cardiomyocytes, phosphorylation of MLC2v by cardiac-MLCK is an essential step for the initiation of sarcomere assembly. Upregulation of the protein levels of cardiac-MLCK in infantile rat heart supports this idea.

In this experimental model, no phenotypic alterations were observed following knockdown of cardiac-MLCK in cultured cardiomyocytes. This apparently paradoxical result occurred because phosphorylation of MLC2v is upregulated in cultured cardiomyocytes until 36 hours after plating, after which it is gradually downregulated. In the siRNA-mediated gene knockdown experiment, a reduction in the cardiac-MLCK protein level that was sufficient to decrease the phosphorylation of MLC2v was only obtained 60–72 hours after isolation. Therefore, by the time the required level of protein suppression was achieved, primary sarcomere assembly had been completed, and the subsequent decreases in MLC2v phosphorylation did not disrupt established sarcomere structures.

Reduction of cardiac-MLCK levels in zebrafish embryos through the injection of z-cMKaugMO resulted in ventral swelling, which has been previously reported to be a representative phenotype of cardiac abnormalities in zebrafish embryos (20, 21). The reliability of the results obtained with z-cMKaugMO was confirmed using multiple MOs that targeted not only cardiac-MLCK but also its substrate, MLC2v. In each experiment, reproducible results were obtained. Another MO that has 5-base mismatch to z-cMKaugMO was also examined as a negative control MO. Further analysis revealed dilatation of the ventricle with a thinned ventricular wall and immature sarcomeres in the morphants. The fragility of the ventricular wall as a result of insufficient sarcomere formation may have caused the ventricular dilatation. Although ventricular function as assessed by FS was preserved in the morphants, this might have been due to some positive inotropic effects, which were suggested by the increased heart rate observed in the z-cMKaugMO morphants. Although several reports have investigated the effects of MLC2v phosphorylation in striated muscle contractions, including in cardiac muscle, the in vivo ventricular role of MLC2v phosphory-

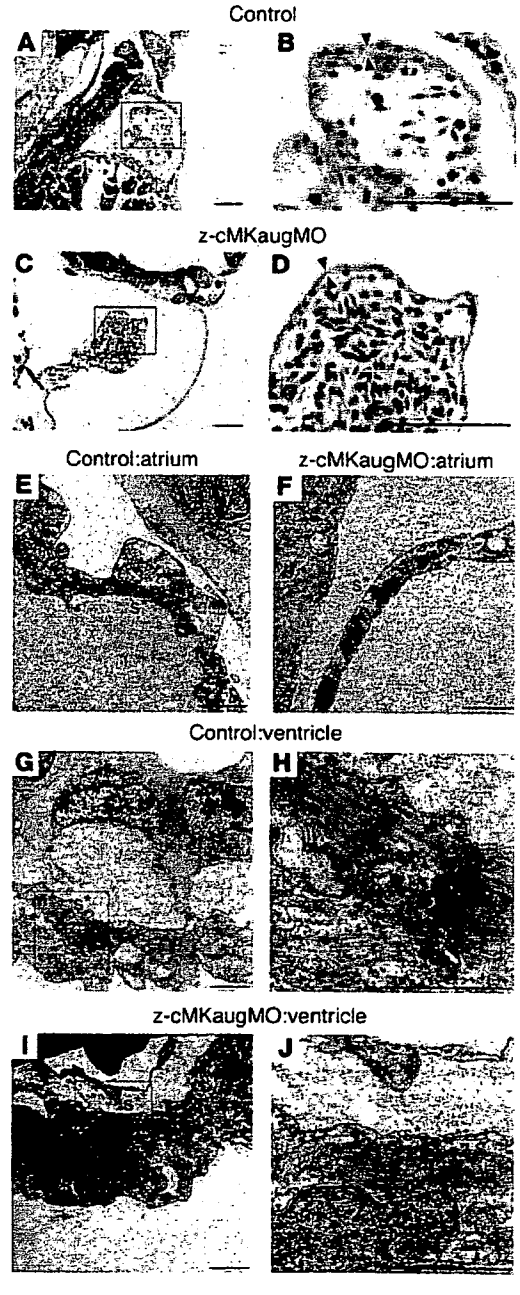

Figure 7
Histology of the zebrafish heart at 48 hpf. (**A–D**) Longitudinal sections stained with hematoxylin and eosin. Scale bars: 50 μm. (**E–J**) Transmission electron micrographs. Scale bars: 2 μm. (**A** and **B**) Histology of control zebrafish hearts at 48 hpf. A relatively thick ventricular wall was apparent (**B**, arrowheads). (**C** and **D**) Pericardial edema and a thinner ventricular wall (**D**, arrowheads) were observed in z-cMKaugMO morphants. (**E** and **F**) In the atria, the sarcomere structures were well differentiated in both the control embryos and the z-cMKaugMO morphants. In the ventricles of control embryos, robust sarcomere structures were observed (**G** and **H**), whereas the ventricles of the z-cMKaugMO morphants contained sparse and immature sarcomere structures (**I** and **J**). Images in **B**, **D**, **H**, and **J** show higher magnifications of the boxed areas in **A**, **C**, **G**, and **I**, respectively. Asterisks denote sarcomere structures (s).

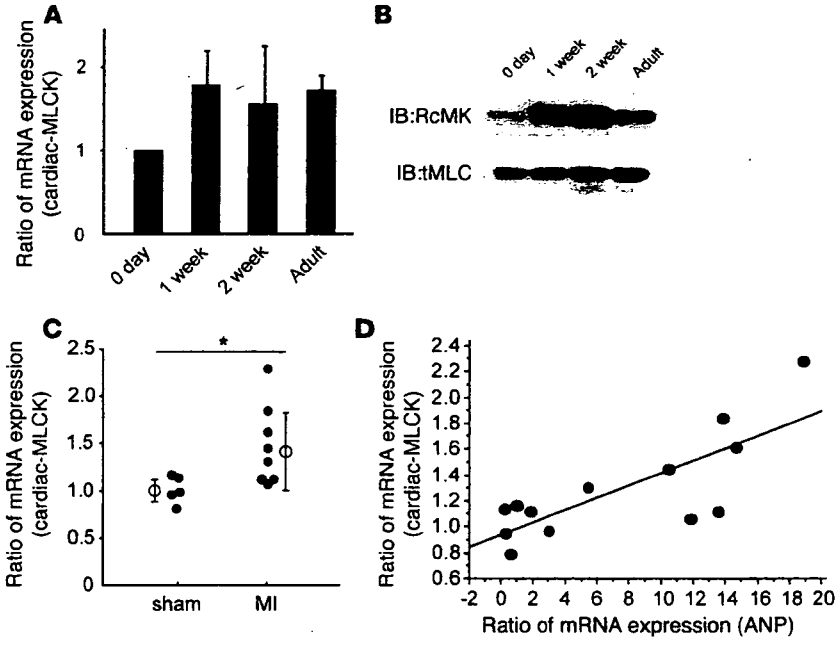

Figure 8
Expression of cardiac-MLCK is upregulated in infantile rat myocardia and failing rat myocardia. (**A**) mRNA expression of cardiac-MLCK was also upregulated in rat myocardia from 1 week after birth to adulthood. The levels of cardiac-MLCK protein were upregulated in infantile myocardia 1–2 weeks after birth. (**B**) The levels of cardiac-MLCK protein were upregulated in infantile myocardia 1–2 weeks after birth. (**C**) mRNA expression of cardiac-MLCK was significantly upregulated in failing rat myocardia. $n = 5$ (sham-operated); 8 (MI). Filled symbols represent values from individual mice; open symbols with bars represent mean ± SEM. $^*P < 0.05$. (**D**) The relative mRNA expression levels of ANP and cardiac-MLCK were significantly correlated ($r = 0.778$; $P < 0.005$).

lation is still not well understood (22, 23). To explore how cardiac-MLCK contributes to ventricular function, other experiments, such as a skinned fiber study, should be performed. A similar cardiac phenotype was reported in a recent study investigating the zebrafish *tel* mutant, in which the gene encoding MLC2v was disrupted by an *N*-ethyl-*N*-nitrosourea-induced mutation. The authors concluded that MLC2v is essential for the assembly of myosin thick filament (24). The observation of incomplete sarcomere formation resulting in a dilated ventricle in zebrafish embryos after injection of z-cMKaugMO can be explained by an inability to initiate sarcomere assembly as a result of reduced cardiac-MLCK levels.

Our results prompt the important question of how cardiac-MLCK is involved in the pathophysiology of CHF. In failing myocardia, decreases in myofibrillar proteins such as titin, myosin, and actin, together with the sarcomere defects, have been identified (25, 26). Reduced expression of MLC2v protein as a result of protease-mediated cleavage and reduced phosphorylation of MLC2v have also been reported in the myocardia of patients with dilated cardiomyopathy. These changes produced unstable, short myofilaments following defective assembly of the myosin thick filaments (27, 28). Our preliminary data also revealed that the protein expression of cardiac-MLCK and the extent of MLC2v phosphorylation were remarkably decreased in failing myocardia of trans-aortic constriction mice compared with those of sham-operated mice. Previous reports and our present results suggest that cardiac-MLCK may be upregulated to compensate for the lower expression and reduced phosphorylation of MLC2v. As a possible therapeutic modality in patients with CHF, upregulation of cardiac-MLCK may promote sarcomere reassembly and enhanced contractility of the failing heart.

Methods

Animals. All procedures were performed in conformity with the *Guide for the care and use of laboratory animals* (NIH publication no. 85-23, revised 1996) and were approved by the Osaka University Committee for Laboratory Animal Use.

Materials. We used commercially available anti-FLAG-M2 antibody and anti-FLAG-M2 affinity gel (Sigma-Aldrich), monoclonal mouse anti-troponin T cardiac isoform antibody (NeoMarkers), monoclonal mouse anti-human desmin Antibody (Dako Corp.), and polyclonal goat anti-α-actinin (N-19) antibody (Santa Cruz Biotechnology Inc.). Epinephrine hydrochloride was purchased from Sigma-Aldrich. We also generate RcMK, anti-human smMLCK, tMLC, and p-s15MLC.

Microarray analysis. For microarray analysis, 2 RNA samples of human normal myocardium and 12 samples of failing myocardium were used. Failing myocardium samples were obtained from severe CHF patients by Batista or Dor operation after obtaining the patients' written informed consent. PAP was measured 2–4 weeks before the operation, and ejection fraction (EF) was measured by echocardiography the day before the operation. Normal samples were purchased from Biochain Inc. Cardiac gene expression was determined using the HG-U95 Affymetrix GeneChip. All expression data were normalized by global scaling and analyzed by GeneSpring software (Agilent Technologies). All expression data were normalized per gene and analyzed after removing noise and unreliable data. PAP, EF, and BNP values were normalized to their median values, and the correlation between gene expression and the clinical parameters was evalu-

Table 3
Hemodynamic and echocardiographic characteristics of MI and sham-operated rats

	Sham	MI	*P*
LVSP (mmHg)	126.8 ± 10.9	125.5 ± 11.0	NS
HR (bpm)	415.4 ± 10.4	407.6 ± 23.0	NS
Max dP/dt (mmHg/s)	9,440 ± 644	5,845 ± 1,156	<0.01
LVEDP (mmHg)	3.2 ± 1.0	20.5 ± 8.2	<0.01
LVDd (mm)	6.8 ± 0.5	9.8 ± 0.3	<0.01
FS (%)	44.0 ± 7.8	12.0 ± 3.1	<0.01

Values are mean ± SEM. $n = 5$ (sham); 8 (MI). LVEDP, LV end-diastolic pressure; LVSP, LV systolic pressure; HR, heart rate; Max dP/dt, LV peak rate of change in pressure during isovolumic contraction.

ated. To further select genes that are expressed almost exclusively in heart, expression values for the candidate genes were retrieved in 24 major tissues for analysis from GeneExpress database (Gene Logic Inc.) containing GeneChip expression profiles of human samples.

RNA extraction, RT-PCR, and quantification. Rat tissues (20–50 mg) and zebrafish embryos at 72 hpf were homogenized in 1 ml RNA-Bee reagent (Tel-Test Inc.), and total RNA was isolated and converted to cDNA using Omniscript RT kit (QIAGEN) according to the manufacturer's instructions. Specific primers to amplify rat ANP, β myosin heavy chain, cardiac-MLCK, and GAPDH mRNA were purchased from Applied Biosystems. Quantitative RT-PCR reactions were run in duplicate using the ABI Prism 7700 Sequence Detector System (Applied Biosystems). The level of each transcript was quantified by the threshold cycle (Ct) method using GAPDH as an endogenous control. For RT-PCR, specific primers that cover the region of targeted exons were designed to amplify the transcripts of z-cardiac-MLCK and z-MLC2v. See Supplemental Methods for primer sequences.

Northern blot analysis. Commercially available human multiple tissue Northern blot and polyA$^+$ RNA of human heart and skeletal muscle were purchased from Clontech. Each polyA$^+$ RNA was reverse transcribed and amplified using an Omniscript RT kit (QIAGEN) according to the manufacturer's protocol. Hybridization probes of human cardiac-MLCK and smMLCK were amplified by PCR from cDNA of human heart, and a hybridization probe of human skMLCK was amplified by PCR from cDNA of human skeletal muscle. Membrane was hybridized to ^{32}P-labeled probe in Rapid-Hyb buffer (Amersham Bioscience) at 65°C for 1 hour. Final wash conditions were 0.1× SSC with 0.1% SDS at 65°C for 5 minutes. Hybridized membrane was visualized by autoradiography using the BAS system (Fuji).

Preparation and transfection of adenovirus constructs. Adenovirus constructs were generated using ViraPower Adenoviral Expression System (Invitrogen) essentially as instructed by the manufacturer. Adenovirus vectors encoding murine cardiac-MLCK and LacZ were infected to cultured cardiomyocytes for 12 hours in various MOIs. Protein collection and immunostaining were performed 48 hours after adenovirus infection.

Identification of the substrate of cardiac-MLCK. Recombinant cardiac-MLCK was expressed in HEK293T cells as FLAG-tagged protein. HEK293T cells expressing FLAG-tagged cardiac-MLCK were lysed with cell lysis buffer (20 mM MOPS, pH 7.0, 0.15 M NaCl, 10% glycerol, and 1% CHAPS) and recombinant cardiac-MLCK was purified by immunoprecipitation using anti-FLAG-M2 affinity gel (Sigma-Aldrich). Hearts dissected from male C57BL/6 mice (10–12 weeks of age) were mechanically homogenized using a Polytron homogenizer in 10 ml of tissue lysis buffer (30 mM MOPS, pH 6.8, 5% glycerol, 0.1% 2-mercaptoethanol, and 1 mM EGTA). Lysate was centrifuged for 40 minutes at 100,000 *g*, and 9 ml of supernatant was collected. Murine heart extracts were then applied to SP650 cation exchange column. The column was equilibrated with elution buffer A (30 mM MOPS, 5% glycerol, 0.1% 2-mercaptoethanol) at pH 6.8, and the extracts were eluted with a linear gradient of NaCl (0–0.5 M) at a flow rate of 1 ml/min. Each 1-ml fraction collected was incubated for 30 minutes with activated recombinant cardiac-MLCK, commercially available recombinant calmodulin (Upstate), 2 mM $CaCl_2$, and [γ-P^{32}]ATP and then subjected to SDS-PAGE. After drying, the gel was autoradiographed and visualized with BAS (Fuji). The fractions containing 20-kDa substrate (fractions 10 and 11) labeled with [γ-P^{32}]ATP were pooled and applied to a phenyl-RPLC column (5Ph-AR-300; nacalai tesque) equilibrated with 0.3% trifluoroacetic acid and 5% acetoritrile. Fractions were eluted with a linear gradient of 100% acetonitrile at flow rate of 1 ml/min. After separation with SDS-PAGE, the gel was simultaneously silver stained and autoradiographed. After identifying the 20-kDa substrate with silver-stained gel, the bands were excised from the gel, and proteins were identified by matrix-assisted laser desorption/ionization-time-of-flight mass spectrometry and peptide mass fingerprinting.

Preparation of cultured neonatal rat cardiomyocytes and gene silencing via RNA interference. Primary cultures of neonatal cardiomyocytes were prepared from Wistar rats as described previously (29). Cardiomyocytes were cultured in DMEM (Sigma-Aldrich) supplemented with 10% FBS (Equitech-Bio). At 6 hours after isolation of cardiomyocytes, cells were transfected with siRNAs (100 nmol/l) using Optifect reagent (Invitrogen) according to the manufacturer's instructions. Both si-cMK (see Supplemental Methods) and si-smMK (see Supplemental Methods) were purchased from B-bridge. As a negative control, cells were transfected with siControl Non-Targeting siRNA#1 (B-bridge). Isolation of mRNA was performed at 24 hours after transfection and protein experiments were performed at 72 hours after transfection. For immunostaining, the same procedures of siRNA transfection were performed in one-fifth scale on Lab-Tek Chamber Slides (nunc).

Cloning of z-cardiac-MLCK. We generated an adult zebrafish cDNA library in Lambda Zap II (Stratagene) using polyA$^+$ RNA from adult zebrafish. The cDNA library was screened with the probe designed to the 5′ side in the ORF of the putative zebrafish ortholog of cardiac-MLCK sequence. Positive phage clone was determined by using phage plaque screen method and single clone excision protocol according to the manufacturer's instructions (Stratagene).

Gene accession numbers. DDBJ accession numbers for the zebrafish MLCK family were as follows: cardiac-MLCK, AB267907; smMLCK, AB267908; skMLCK, AB267909.

Whole-mount in situ hybridization. The digoxigenin-labeled antisense and sense RNA probes (see Supplemental Methods) were transcribed using SP6 and T7 RNA polymerase. Zebrafish embryos at 24 and 48 hpf were fixed with 4% paraformaldehyde, digested with proteinase K, and hybridized with each probe at 68°C. Alkaline-conjugated anti-digoxigenin antibody was used to detect the signals. After staining, embryos were refixed with 4% paraformaldehyde and stored in PBS.

Injection of MO. All MOs were synthesized by Gene-Tools. At cell stages 1–4, 4–10 ng of these MOs were injected into zebrafish embryos. Several data were collected before the 96-hpf stage. Sequences of MOs are available in the Supplemental Methods.

Analysis of zebrafish cardiac histology and cardiac function. We studied hearts of control mock-injected zebrafish embryos and z-cMKaugMO-injected zebrafish embryos at 72 hpf by routine histopathology including transmission electron micrography. To visualize the motion of zebrafish cardiac ventricle, the SAG4A strain of zebrafish, which specifically expresses GFP in its cardiac ventricular wall (14), was applied to MO-mediated gene knockdown experiments. GFP-expressed control mock-injected and z-cMKaugMO-injected zebrafish hearts at 72 hpf were imaged with Leica digital camera DFC 350 FX on a Leica MZ 16 FA fluorescence stereomicroscope. Acquired images were compiled as digital movie files using Leica FW4000 software. Each recorded movie was converted to M-mode image using our original software, and Dd, Ds, FS, and heart rate were measured from the M-mode images.

Experimental protocols of rats. Male Wistar rats (0 days, 1 week, 2 weeks, and 10 weeks for mRNA and protein expression analysis; 8 weeks for production of MI rats; Japan Animals) were used in these experiments. MI was induced by permanent ligation of the left anterior descending coronary artery as previously described (29). The same surgical procedure was performed in a sham-operated group of rats except that the suture around the coronary artery was not tied. Isolation of total RNA was performed at 4 weeks after the onset of MI from noninfarcted myocardiums of resected LVs.

Statistics. Statistical analysis was performed using Mann-Whitney *U* test and single regression analysis. Data are presented as mean ± SEM. A *P* value less than 0.05 was considered significant.
