their proliferation. All results were expressed as mean values ± SD and were analyzed statistically with Student's t test.

Results

XRD patterns of the precipitates prepared in this study are shown in Fig. 1. The XRD indicated that precipitates with Nb/(Nb + P) molar ratios from 0 to 0.167 had a monolithic apatite structure, irrespective of the Nb/(Nb + P) molar ratio of the starting solution, although the level of crystallite decreased as the Nb content increased. XRD patterns of the precipitates with various Nb/(Nb + P) molar ratios annealed at 800°C are shown in Fig. 2. The level of crystallites of the precipitates was high due to the annealing, and their diffraction peaks were composed of those of both HAp and

β-TCP. Interestingly, the crystallite level decreased when the Nb level increased.

The chemical compositions and characteristics of the precipitates prepared in this study are summarized in Table 1. Both the Ca/(Nb + P) and the Nb/(P + Nb) molar ratios in precipitates measured by ICP approximately agreed with their theoretical values, except for the Nb/(P + Nb) molar ratio of NbTCP/HAp-II: the measured Nb/(P + Nb) molar ratio of NbTCP/HAp-II was 0.074, which is lower than the theoretical value of 0.167. The lattice parameter of the HAp phase in NbTCPHAp increased with increasing Nb content.

Fig. 3. Scanning electron microscopy–energy-dispersive X-ray spectroscopy spectra of NbTCP/HAp-II annealed at 800°C (a) and their mapping images from P-Kα, Ca-Kα, and Nb-Mα lines (b)

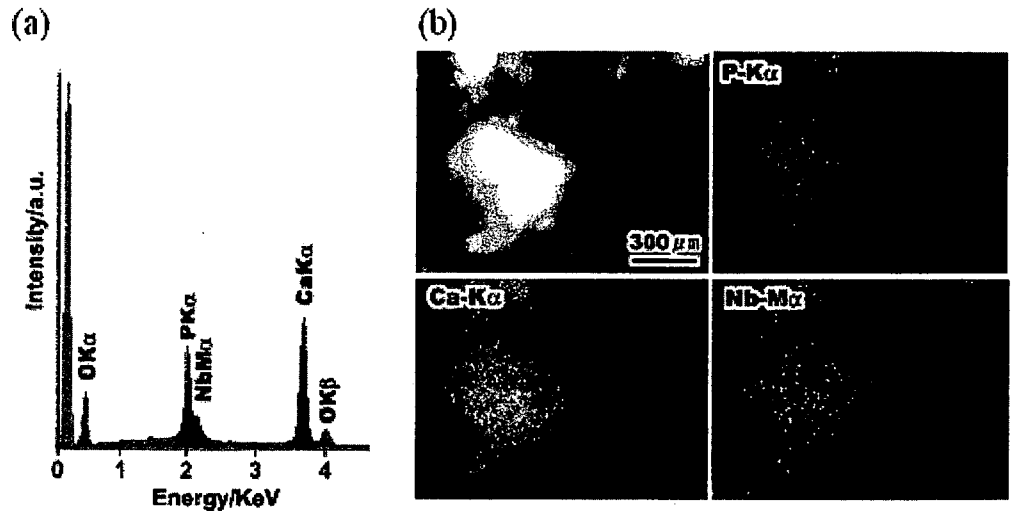

Fig. 4. Proliferation and alkaline phosphatase (*ALP*) activity of normal human osteoblasts (NHOst) cultured on various kinds of NbTCP/HAp pellets. *$P < 0.01$ against NbTCP/HAp-0 (without Nb ions)

The lattice parameters of NbTCP/HAp-0 without Nb ions were 0.939 nm for the a-axis and 0.687 nm for the c-axis, while those of NbTCP/HAp-II were 0.943 nm for the a-axis and 0.690 nm for the c-axis. In addition, the color of the precipitates became dark yellow as the Nb/(P + Nb) molar ratio increased, while the annealed precipitates of NbTCP/HAp were white.

SEM observation of the precipitates before annealing revealed that all precipitates were present as aggregates composed of primary particles of less than 1 μm in diameter, irrespective of the Nb/(P + Nb) molar ratio. Figure 3a shows SEM-EDX spectra of NbTCP/HAp-II. The EDX spectrum of Nb Mα was separated from the P Kα line and could be observed at 2.17 KeV, although its intensity was weak. The mapping images of the P-Kα, Ca-Kα, and Nb-Mα lines are shown in Fig. 3b. As shown in Fig. 3b, Nb ions were present at the same site as the Ca and P ions, suggesting that the Nb ions were homogenously distributed in the aggregates.

The proliferation and ALP activity of NHOst cultured on various kinds of NbTCP/HAp pellets is shown in Fig. 4. The proliferation of NHOst cultured on NbTCP/HAp-II pellets was approximately 60% higher than that on NbTCP/HAp-0 without Nb ions ($P < 0.01$). As shown in Fig. 5, many
Fig. 5. Light microscopic images of NHOst cultured on various NbTCP/HAp samples for 7 days: *a*, NbTCP/HAp-0; *b*, NbTCP/HAp-I; and *c*, NbTCP/HAp-II. NHOst were stained by Giemsa solution
Fig. 6. Osteogenic properties (proliferation, ALP activity, and Ca deposition) of NHOst cultured in extracts from various NbTCP/HAp samples for 14 days. $*P < 0.01$ against NbTCP/HAp-0 (without Nb ions)

Fig. 7. Concentrations of Nb ions in extracts from various NbTCP/HAp samples. The concentration of Nb ions in cell culture medium was measured by inductively coupled plasma analysis

NHOst adhered to and spread on NbTCP/HAp-I and -II, while little spreading of NHOst was observed on HAp. In addition, as shown in Fig. 4, NHOst cultured on the NbTCP/HAp-II pellets expressed high ALP activity, compared with those cultured on NbTCP/HAp-0. Figure 6 shows the proliferation, ALP activity, and Ca deposition of NHOst cultured in extracts from various NbTCP/HAp samples for 14 days. Like the NHOst cultured on pellets, NHOst cultured in the extract from NbTCP/HAp-II expressed higher ALP activity than those in the extract from NbTCP/HAp-0. Furthermore, the amount of deposited calcium from NHOst increased with increasing Nb ion concentration in NbTCP/HAp, and the calcium deposition in the extract from NbTCP/HAp-II was twice that in the extract from NbTCP/HAp-0.

Figure 7 shows the concentration of Nb ions in extracts from NbTCP/HAp samples. It was found that Nb ions were released into the cell culture medium at concentrations of the order of 1×10^{-5} mol/l. To investigate the effect of Nb ions on NHOst function, NHOst were cultured in a medium containing Nb ions. The dependence of osteogenesis by NHOst on Nb ion concentration is shown in Fig. 8. Nb ions did not affect the proliferation of NHOst, but the ALP activity and Ca deposition of NHOst proceeded proportionally when the concentration of Nb ions was more than 1×10^{-5} mol/L.

Discussion

Characterization of NbTCP/HAp biphasic calcium phosphate ceramics

As summarized in Table 1, before annealing the precipitates, the NbHAp samples were hydroxyapatite with low levels of crystallite. The hydroxyapatite structure is known to be very tolerant of ionic substitution.[12] Ca^{2+} ions, PO_4^{3-} ions, and OH^- ions can be replaced, partly or completely, by various cationic or anionic ions. Notably, as shown in Table 1, the lattice parameter of HAp increased when the

Concentration of Nb ions in culture medium (mol/L)
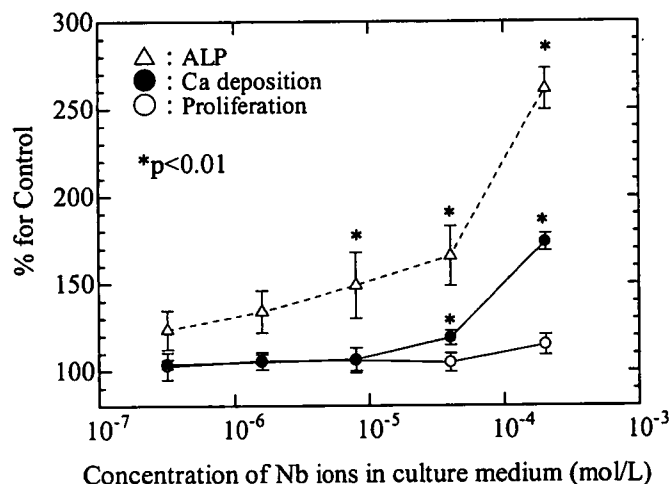

Fig. 8. Relationship between concentration of Nb ions in culture medium and osteogenic properties of NHOst. $*P < 0.01$ against cell culture medium without Nb ions

Nb content in NbTCP/HAp was high. This fact suggests that Nb ions are taken into the apatite lattice. If a substitution of an Nb^{5+} ion for a Ca^{2+} ion in HAp occurred, the lattice parameter should decrease, since the ionic radius of Ca^{2+} and Nb^{5+} are 0.1 nm and 0.064 nm, respectively. Therefore, the possibility of substitution of Nb ions for Ca ions is low. On the other hand, although the structure of Nb ions in aqueous solution is not fully understood at present, it has been reported that Nb ions in solution are not present as Nb^{5+} but as niobiumate acid, $H_xNb_6O_{19}^{(8-x)-}$ ions (x = 0,1,2) for basic conditions,[14,15] and the niobiumate acid cluster ($H_xNb_6O_{19}^{(8-x)-}$) was polymerized or dissociated depending on the pH and ion concentration.[15] According to these reports, $H_4NbO_6^{3-}$ anionic monomer can exist in basal and low Nb concentrations (<0.08M). Since the Nb concentration in this study was 0.01 M, Nb ions would exist as $H_4NbO_6^{3-}$ anionic monomers. $H_4NbO_6^{3-}$ may be substituted at the PO_4 site since the PO_4 site in HAp can be replaced by anionic

atomic groups. In addition, the ionic radius of the $H_4NbO_6^{3-}$ monomer and PO_4 are approximately 0.30 nm and 0.23 nm, respectively, suggesting that an increase in lattice parameter of NbTCP/HAp is ascribed to the substitution of PO_4 sites by this monomer in HAp. Furthermore, the fact that both the Ca/(Nb + P) and Nb/(P + Nb) molar ratios of the precipitates, as measured by ICP, approximately agreed with their theoretical values may support this hypothesis. Despite the theoretical Nb/(Nb + P) ratio being 0.1667, the Nb/(Nb + P) molar ratio in NbTCP/HAp-II was about 0.07, which suggests that the maximum amount of substituted Nb ions at the PO_4 site is around 0.07.

The Ca/(P + Nb) molar ratio in the NbHAp obtained in this study was lower than that of the stoichiometric value of 1.67 for HAp. Hydroxyapatite having a lower Ca/P molar ratio is known as calcium-deficient hydroxyapatite [Ca-def HAp, $Ca_{10-z}(HPO_4)_z(PO_4)_{6-z}(OH)_{2-z}$, Z = 0-1]. Therefore, NbHAp can be regarded as a Ca-def HAp in which the PO_4 sites are partly occupied by Nb ions.

Ca-def HAp decomposes to stoichiometric HAp and β-TCP at temperatures above 600°C according to the following reaction:[16,17]

$$Ca_{10-z}(HPO_4)_z(PO_4)_{6-z}(OH)_{2-z} \cdot nH_2O \rightarrow$$
$$(1 - Z)Ca_{10}(PO_4)_6(OH)_2 + 3Z \cdot \beta\text{-}Ca_3(PO_4)_2 + Z \cdot nH_2O$$
The above thermal decomposition reaction occurred during the annealing of NbHAp, resulting in a lower Ca/P molar ratio than the stoichiometric value of HAp because of partial β-TCP formation. In addition, the homogenously distributed Nb ions in NbTCP/HAp may result from thermal diffusion of Nb ions during the thermal decomposition process.

Osteogenesis of NHOst cultured on NbTCP/HAp

In this study, NbTCP/HAp showed potential to promote calcification of NHOst. This study indicated that osteogenic behavior of NHOst cultured on NbTCP/HAp pellets was consistent with that of NHOst cultured in extracts from the pellets, suggesting that dissolved ions from the NbTCP/HAp pellets affect calcification of NHOst. As shown in Fig. 7, Nb ions were apparently released from NbTCP/HAps and dissolved in the medium at concentrations of the order of 1×10^{-5} mol/l. When 4×10^{-5} mol/l of $NbCl_5$ was added to the culture medium, Ca deposition clearly increased (Fig. 8). Therefore, the enhancement of Ca deposition is considered to be due to the dissolved Nb ions. One possible mechanism for enhancement of calcification is discussed below.

ALP is known to play an important role in the calcification of bone.[18-20] Generally, the calcification of bone mineral occurs in the matrix vesicles budding from the surface of osteoblasts.[21] The nucleation of biological apatite, which is the initial stage of calcification, occurs due to the reaction between inorganic PO_4^{3-} ions produced by the ALP and calcium ions in matrix vesicles.

NHOst cultured on the NbTCP/HAp pellets containing Nb ions expressed high ALP activity compared with those cultured on HAp without Nb ion. Similarly, it was found that NHOst cultured in an extract from NbTCP/HAp containing Nb ions expressed higher ALP activity than those in the extract from HAp without Nb ions. These results suggest that Nb ions affect the enhancement of ALP activity. Based on the above calcification mechanism in matrix vesicles, the enhancement of calcification might result from the enhancement of ALP activity due to dissolved Nb ions from NbTCP/HAp. The enhancement of ALP activity increases the production of inorganic PO_4^{3-} ions, and then the inorganic PO_4^{3-} ions produced may be taken into the matrix vesicles. The subsequent nucleation of biological hydroxyapatite occurs due to a reaction of Ca ions and inorganic PO_4^{3-} ions, followed by calcification. Although we cannot deny that Nb ions directly promote calcification by NHOst unrelated with ALP expression, the essence of the calcification enhancement by NbTCP/HAp may be the enhancement of ALP activity by Nb ions dissolved from NbTCP/HAp. The biological effect of Nb ions on NHOst is under investigation. Although further studies are necessary to clarify the mechanism of enhanced calcification by Nb ions, this study strongly suggests that NbTCP/HAp is a more promising material for use as a bone tissue engineering scaffold than HAp.

Conclusion

In order to promote the osteogenicity of osteoblasts, we synthesized a combination of HAp and β-TCP biphasic calcium phosphate containing Nb ions (NbTCP/HAp). The NbTCP/HAp samples were prepared by annealing precipitates obtained by coprecipitation of an aqueous solution of $Ca(NO_3)_2$ with a mixture of $(NH_4)_2HPO_4$ and aqueous Nb solution. The precipitates obtained by the coprecipitation process can be identified as Ca-def HAp, the PO_4 sites of which are partly occupied by Nb ions. NbTCP/HAp samples were successfully obtained by thermal decomposition of the precipitates.

NbTCP/HAp enhanced calcification of NHOst. The enhancement of calcification of NbTCP/HAp was ascribed to the enhancement of ALP activity due to the dissolved Nb ions from NbTCP/HAp.

Analysis of Stress States in PS Type Knee Prostheses under Dynamic Motion.

Mitsugu TODO, PhD., Ryuji NAGAMINE, MD., Shota YAMAGUCHI

Abstract

Using CAD data, 3-D finite element models of two kinds of PS-type knee prostheses, the first model and the second model, were constructed using a nonlinear spring model and analytical load data for deep squatting. The first model was previously used in TKA, and the second model is the most recent version with a modified design of the Post. Stress analysis was then performed by finite element analysis (FEA) under dynamic flexion motion from 0 to 135 degree. It was shown that only the condyle surfaces of the femoral component and the tibial insert contacted each other from 0 to 60 degrees of flexion for both models, and the stress concentration in the second model was a bit higher than that in the first model. The FEA results also exhibited that severe stress concentration was generated at the Post of the tibial UHMWPE insert due to the Post/Cam contact. This kind of stress concentration may result in the deformation and failure of the Post. It was shown that the design modification applied to the latter model effectively reduced the stress concentration of the Post.

Key words : Total knee arthroplasty, UHMWPE insert, deep flexion, finite element analysis.

緒　　言

重度の変形性膝関節症の患者に対しては，人工膝関節全置換術（total knee arthroplasty；TKA）を行うことで患者のQOLが大幅に回復される．人工膝関節の高機能化のためにはTKAを施した膝関節の人体内での動作状態を詳細に把握し，設計へ反映させることが重要であるが，その動きは屈曲，内外旋，ロールバックなどの運動が複合的に生じており，完全には把握されていないのが現状である．そのため複合動作状態での過度の応力集中による脛骨インサートの疲労破壊や磨耗，またPost-Cam機構に特徴を持つPS型人工膝関節においては，脛骨インサートのPostの損傷などが重要な問題となっている．したがって，脛骨インサートにおける応力状態を知ることが重要であり，有限要素解析（finite element analysis；FEA）による動作状態における応力解析が有用な知見を与えると考えられる．しかし，これまでに行われたTKAの3次元FEAのほとんどは歩行解析を対象としており[1), 2)~5), 8)]，一部深屈曲を考慮した解析は行われているものの[9)]，ある特定の屈曲角度に対して静的解析を行ったのみであり，連続的に立位から深屈曲までの動作を解析した例はほとんど行われていない．筆者らの研究グループは，これまでCADデータを用いた3次元FEAモデルの構築と，深屈曲や回旋を含む動作状態での応力解析について研究を進めてきた[10, 11)]．なお，人工関節でみられるような高度の接触運動について陰解法FEAと陽解法FEAで解析し比較検討してきたが，陰解法では対応できないことが多く，陽解法の方が適応範囲が広いため，本解析でも陽解法汎用FEAコードの

LS-DYNAを用いて屈曲解析を行った．

本研究では，旧型と新型の2種類のPS型人工膝関節のCADデータより3次元FEAモデルを構築し，非線形スプリングモデルおよびスクワットの荷重データを利用することで，立位から深屈曲までにいたる動作状態での脛骨インサートの応力状態を解析した．得られた結果を用いて，広範囲での屈曲が脛骨インサートの顆部およびPostの応力状態に及ぼす影響を詳細に調べ，旧型と新型を比較することで応力状態に及ぼすデザインの影響ならびに深屈曲への適応性について考察した．

有限要素解析モデルの構築

今回解析で用いた2種類のPS型人工膝関節は，過去に使用されていたモデル（1stモデル），および現在使用されているモデル（2ndモデル）である．2ndモデルは1stモデルの改良型とみなすことができ，特に脛骨インサートのPostならびに大腿骨コンポーネントのCamについて形状が変更されている．Postについては角部をなだらかにすることで丸みをもたせ，また，顆部とPostの境界部に溝を導入している．CamについてはPostと接触する面積をより大きくしており，これらの形状の変更により応力集中の低減を図っている．これら2機種のモデルのCADデータを基に，大腿骨コンポーネント，脛骨インサート，および脛骨コンポーネントから構成される3次元FEAモデルを構築した．ここで，大腿骨コンポーネントにおいて，脛骨インサートと接触する箇所（顆部）以外の微小な部分や，脛骨コンポーネントのステムなどは，解析結果にほとんど影響を与えないため，取り除いて簡略化を行った．簡略化した

いが，60deg以降は急激に増加し，最終的に12mm程度の変位が生じている．なお，2機種の間での差は殆どみられない．この60deg以降でみられるバネモデルの変位，すなわち脛骨コンポーネントの－Y方向への移動がロールバックに対応する．

図8に脛骨インサート顆部とPost部での最大相当応力の推移を示す．顆部での応力（図-（a））を比較すると，60deg以下では2ndモデルの方が1stモデルより大きく，120deg以上になると1stモデルの方が大きな応力を示すが，後述のPost部に比べると全体的にその差は小さかった．2ndモデルの脛骨コンポーネントの前顆部の傾斜は，1stモデルよりも若干緩やかであり，そのため60deg以下では，大腿骨顆部との接触がより点接触に近くなり応力が高くなったと考えられる．後顆部の傾斜は両機種でほとんど同じであるため応力の差も小さかった．次にPost部での応力（図-（b））を比較すると，Post-Camの接触が1stモデルでは64degから始まっているのに対して，2ndモデルでは54degから始まっていることが分かった．この差は2ndモデルのPost形状が1stモデルに比べて太くなっているためであると推測される．100degまでは2ndモデルの方が1stモデルより高い応力を示すが，100deg以上では，1stモデルにおける応力集中が急激に増加し大小関係は逆転した．1stモデルは2ndモデルに比べてPost/ Camの接触面積が小さいためこのような急激な応力集中が起きていることが予想される．なお，図-（a）において応力値が変動しているが，これはバネ要素を取り付けた頸骨コンポーネントの振動，頸骨インサート中の応力波の反射などの動的効果の影響によるものと考えられる．

Subtracted Vortex Centers Path Line Method with Cinematic Angiography

for Measurement of Flow Speed in Cerebral Aneurysms

Abstract :

Background and Purpose: The assessment of blood flow speed by imaging

modalities is of increasing importance for endovascular treatment, such as stent

implantation, of cerebral aneurysms. The subtracted vortex centers path line

method (SVC method) utilizes image post-processing for determining flow

quantitatively. In current practice, intraaneurysmal flow in an in-vitro model is

visualized by laser sheet translumination and digitally recorded. In this study, we

applied this method to cinematic angiography (CA), which is the preferred

imaging method for endovascular interventions, to analyze hemodynamic

changes. The SVC method was applied to the images and compared with results of the slipstream line method with colored fluid.

Methods: A transparent tubular model was constructed of silicone which included an aneurysm 10 mm in diameter and having a 5 mm neck on a straight parent artery with a diameter of 3.5 mm. The model was integrated into a pulsatile circulation system. By CA, successive images at 25 frames per second with injection of contrast were obtained.

Results and conclusion: Rotating vortexes of contrast, which advanced along the wall of the aneurysm, were observed in successive images of the aneurysm cavity. This phenomenon was also observed in the successive images with the slipstream line method. The speed of the vortex center was calculated and the results show that the vortex speed of CA was the same as that under the slipstream line method. This indicates the possibility of applying the SVC method to medical imaging equipment for analysis of the flow in aneurysms containing stent.

Introduction

With the availability of flexible stent placement for intracranial aneurysms, this relatively new treatment is recently being increasingly utilized (1-4). By decreasing the inflow into the aneurysm, stent treatment may lead to thrombus formation in intracranial aneurysms (5-10). The stent design, e.g., the design of the stent edge, critically impact on flow changes (11, 12).

The assessment of blood flow by imaging modalities is of increasing importance. Magnetic Resonance (MR), Computed Tomography (CT), or Digital Subtraction Angiography (DSA) are the three major techniques currently being applied for this purpose.

Wakhloo et al. used Ethiodol droplets for measurement of flow in arteriovenous malformations (AVM) (14). Isoda et al., for example, have investigated time-of-flight MR angiography in aneurysm models which enables the three-dimensional measurements (13). To evaluate intraaneurysmal hemodynamics using images acquired by DSA, Sadasivan et al. (15) and Asakura et al. (16) utilized time-density curves, and Sadasivan described the convection and diffusion components of flow and quantified the changes in flow in cerebral aneurysms after stents implantation.

The subtracted vortex centers path line (SVC) method was developed by Cassot and Barath, where an in vitro pulsatile circulation loop was seeded with particles and illuminated by a laser-sheet for measuring flow speed in a side-wall aneurysm model (17). In this SVC method, post-processing of successive images is employed to trace a rotating vortex of particles from which the speed of the vortex movement in the aneurysm can be determined. This vortex speed represents intraaneurysmal flow speed, which is a parameter that can be used for evaluating medical devices such as stents (18). Although this processing is very simple and easily employed in the clinical field, it has only been used with in-vitro setups, but never under in vivo conditions or by clinicians.

In this study, the SVC method was applied to successive contrast images acquired with cinematic angiography (CA). The distance which a vortex moved was compared with a slipstream line acquired by video to validate and confirm the feasibility of integrating this method in medical imaging devices.

Materials and methods

In-vitro model:

A transparent tubular model made of silicone (ELASTRAT Sarl., Geneva, Switzerland) including an aneurysm with a 5 mm neck and a diameter of 10 mm, which was situated on a straight parent artery 3.5 mm in diameter (Figure 1), was integrated into a circulation system. This model was based on the previous paper (17) to compare to the results. The pressure and the pulsatility (143/77 mmHg and 1 Hz, respectively) were measured at the injection point in the system (the flow rate was 200 ml / min). Water was used as fluid at room temperature. For varying the flow pattern in the aneurysm, a stent (Leo stent, 4 mm diameter, 1.5 cm long, BALT) was prepared and the flow speeds before and after its placement were measured.

Image acquisition:

CA

The image acquisition rate of CA (3D-RA, BV 3000, Philips Medical Systems

(PMS), The Netherlands) was 25 frames per second using imaging parameters

of 60 kV and 300 mA. Each successive image was 512×512 bits in a 18.415 cm

square with a 256 grayscale.

Slipstream line method

To compare images based on contrast with CA, a slipstream line was obtained

by a video camera. Red hydrophilic liquid was introduced into the same

circulation. The rate of the camera (DSC-T1, SONY, Japan) was 30 frames per

second.

Post-processing

The SVC method was applied to the flow images of CA and the slipstream line,

respectively, to quantify the flows.

All procedures of this processing were performed with commercially available

based software packages which can be easily accessed by clinicians. Microsoft

Photo Editor 3.01 (Microsoft Corporation, USA) was used for enhancement of

image and subtraction was performed on JASC Paint Shop Pro 6.00 (Jasc

Software, USA). Tracing the vortex center was carried out with NIH images
