#### ABSTRACT

$\alpha$ -Helical peptides, such as T-20 (enfuvirtide) and C34, derived from the gp41 carboxyl-terminal heptad repeat (C-HR) of HIV-1, inhibit membrane fusion of HIV-1 and the target cells. Although T-20 effectively suppresses the replication of multi-drug resistant HIV variants both in vitro and in vivo, prolonged therapy with T-20 induces emergence of T-20 resistant variants. In order to suppress the emergence of such resistant variants, we introduced charged and hydrophilic amino acids, glutamic acid (E) and lysine (K), at the solvent accessible site of C34. In particular, the modified peptide, SC34EK, demonstrates remarkably potent inhibition of membrane fusion by the resistant HIV-1 variants as well as wild-type viruses. The activity was specific to HIV-1 and little influenced by serum components. We found a strong correlation between the anti-HIV-1 activities of these peptides and the thermostabilities of the 6-helix bundles that are formed with these peptides. We also obtained the crystal structure of SC34EK in complex with a 36 amino acid sequence (N36) comprising the amino-terminal heptad repeat of HIV-1. The EK substitutions in the sequence of SC34EK were directed toward the solvent and generated an electrostatic potential, which may result in enhanced  $\alpha$ -helicity of the peptide inhibitor. The 6-helix bundle complex of SC34EK with N36 appears to be structurally similar to that of C34 and N36. Our approach to enhancing  $\alpha$ -helicity of the peptide inhibitor may enable future design of highly effective and specific HIV-1 inhibitors.

#### 1. Introduction

Enfuvirtide (T-20), which has been clinically approved as the first fusion inhibitor of HIV-1, is derived from a 36 amino acid region of the carboxyl-terminal heptad repeat (C-HR) of gp41, an HIV-1 transmembrane envelope glycoprotein, which plays central role in the fusion of HIV-1 with host cells. T-20 prevents the formation of a 6-helix bundle, which is comprised of a trimer of dimers formed from the amino-terminal heptad repeat (N-HR) and the

carboxyl-terminal heptad repeat (C-HR) in an antiparallel orientation. Six-helix formation by physiological gp41 enables host cell and virus membranes to contact and fuse, enabling the virus entry into the cells. Therefore, inhibition of the formation of this 6-helix bundle prevents fusion of HIV-1 and targeted host cell membranes (Derdeyn et al., 2000; Wild et al., 1992). Notably, T-20 effectively suppresses the replication of HIV-1 variants, which are resistant to multiple reverse transcriptase and protease inhibitors, and has been used in the optimized regimens for HIV-1-infected patients harboring multi-drug resistant HIV-1 variants (Lalezari et al., 2003; Lazzarin et al., 2003).

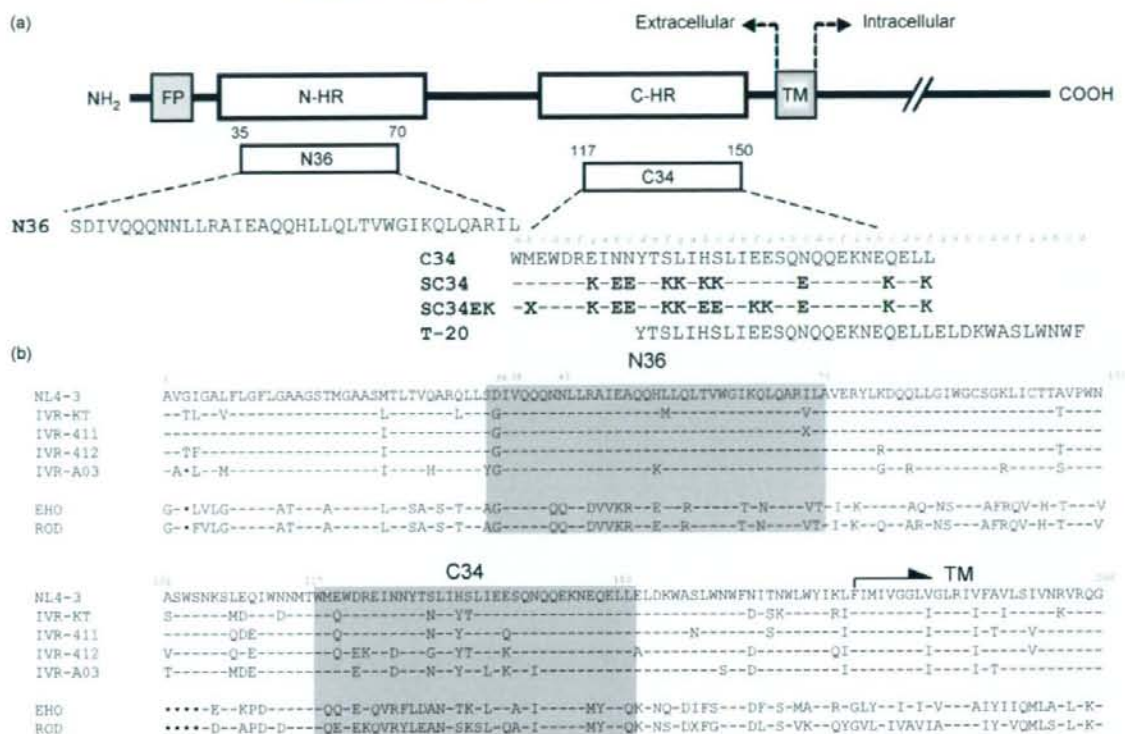

Emergence of T-20-resistant HIV-1 was reported not only in patients receiving T-20 monotherapy in a phase I clinical trial (Wei et al., 2002), but also in patients treated with a combination of T-20

**Fig. 2.** Schematic view of gp41 and C34 derivatives and amino acid alignment of gp41. (a) The locations of the fusion peptide (FP), the amino-terminal heptad repeat region (N-HR), the carboxyl-terminal heptad repeat region (C-HR), and the transmembrane domain (TM) and the amino acid sequences of N36, T-20, C34 and its derivatives are shown. The residue numbers of each peptide correspond to their positions in gp41 of the NL4-3 strain. The X in SC34EK indicates norleucine, introduced to avoid oxidation of the methionine residues. No differences between the original methionine- and norleucine-containing peptide were observed (Otaaka et al., 2002). (b) Alignment of amino acid sequence of clinical isolates (KT, IVR411, IVR412 and IVR-A03; GenBank accession number: AB222704, AB222705, AB222706 and AB222703, respectively) and HIV-2 strains (EHO and ROD) are shown. Corresponding regions of N36 and C34 are indicated in gray. Identical or deleted amino acids from the sequence of NL4-3 are indicated with a bar or a dot, respectively. The X in amino acid sequences of IVR411 and ROD indicates the mixture of I and V for IVR411, and mixture of I and M for ROD.

tively. HeLa-CD4-LTR- $\beta$ -gal cells were kindly provided by Dr. M. Emerman through the AIDS Research and Reference Reagent Program, Division of AIDS, National Institute of Allergy and Infectious Disease (NIAID) (Bethesda, MD) and were used for the drug susceptibility assay (MAGI assay) as described previously (Kimpton and Emerman, 1992; Kodama et al., 2001; Maeda et al., 1998). The activity of test compounds was determined as the concentration that blocked HIV-1 replication by 50% ( $EC_{50}$ ).

Laboratory HIV-1 (III<sub>B</sub>) and HIV-2 (EHO and ROD) strains were used. An HIV-1 infectious clone pNL4-3 was used for constructions and for the production of HIV-1 variants as described (Nameki et al., 2005). A wild-type HIV-1, HIV-1<sub>WT</sub>, was generated by transfection of pNL4-3 into 293T cells. Clinical isolates obtained from drug-naïve and heavily drug-experienced patients, were kindly provided by Dr. S. Oka (AIDS Clinical Center, International Medical Center of Japan, Tokyo, Japan). Their co-receptor tropisms were determined using NCK45 cells as described previously (Kajiwaru et al., 2006).

## 2.2. Antiviral agent

The peptide-based fusion inhibitors used in this study were synthesized as described previously (Otaaka et al., 2002), and the sequences can be identified in Fig. 2a. 3'-Azido-3'-deoxythymidine (AZT) and 2',3'-dideoxycytidine (ddC) were purchased from Sigma

(St. Louis, MO, USA). MKC-442 was provided by Dr. S. Shigeta (Fukushima Medical University, Fukushima, Japan).

## 2.3. Determination of drug susceptibility of HIV-1

The peptide sensitivity of infectious clones was determined using the MAGI assay with as described previously (Kodama et al., 2001; Maeda et al., 1998). The activity of test compounds was determined as the concentration that blocks HIV-1 replication by 50% ( $EC_{50}$ ). For clinical isolates, PHA-stimulated peripheral blood mononuclear cells (PBMCs) were used as described previously (Kodama et al., 2001). PBMCs ( $10^6$  cells/ml) were exposed to test compounds and HIV-1, and were cultured in the presence of interleukin 2 for 7 days. Amounts of p24 protein in the supernatants of the cultures were then determined using the commercially available p24 antigen enzyme linked solvent assay kit.

## 2.4. Construction of recombinant HIV-1 clone

Recombinant infectious HIV-1 clones with substituted V3 regions, pNL-V3<sub>ADA</sub> and pNL-V3<sub>SE162</sub> were generated using pNL4-3. The V3 region, corresponding to n.t. 7029–7249 of pNL4-3, was amplified using primers containing appropriate BglII and NheI restriction enzyme cleavage sites for directional cloning into pBS-

<sup>a</sup> Anti-HIV-1 activity was determined using the MAGI assay. All data represent means ± standard deviation obtained from the results of three independent experiments. Bold indicates over 5-fold increase in EC<sub>50</sub> value compared to HIV-1<sub>WT</sub>.

<sup>b</sup> The co-receptor tropism was determined using NCK45 cells as described (Kajiwarra et al., 2006).

<sup>c</sup> HIV-1<sub>NL4-3</sub> served as a wild-type virus.

<sup>d</sup> ΔFNSTW is the deletion of five amino acids at position 364–368 in the gp120 V4 region of HIV-1<sub>NL4-3</sub> (Nameki et al., 2005). Fusion inhibitor resistant variants used have been previously reported (Armand-Ugon et al., 2003; Nameki et al., 2005).

<sup>e</sup> The V3 region of NL4-3 gp120 was replaced with the corresponding region of HIV-1<sub>SF162</sub>.

<sup>f</sup> HIV-1<sub>V3-CH1</sub> has mutations in the gp120 V3 region of primary isolate HIV-1<sub>KMT</sub>, where GKI is substituted by GEL.

<sup>g</sup> HIV-1<sub>V3-CH2</sub> has mutation in the gp120 V3 region of the primary isolate HIV-1<sub>KMT</sub>, where GKI is substituted by GQL.

gp120<sub>WT</sub>. The resulting amplified V3 region was subjected to BglII and NheI digestion, subcloned into pBS-gp120<sub>WT</sub> containing the corresponding region in the DNA fragment of EcoRI–NheI (1510 bp containing gp120 V1, V2 and V3, n.t. 5740–7249 of pNL4-3) and subsequently ligated into pNL4-3, pNL-V3<sub>CH1</sub> and V3<sub>CH2</sub>, CCR5 and dual (CXCR4 and CCR5) tropic molecular clones, were kindly donated by Dr. Y. Maeda, Kumamoto University (Kumamoto, Japan) (Foda et al., 2001; Maeda et al., 2000).

Recombinant infectious HIV-1 clones carrying various mutations in gp120 and/or gp41 were also generated using pNL4-3. Briefly, the desired mutations were introduced using site directed mutagenesis into the region of pSL-gp41<sub>WT</sub> flanked by the NheI–BamHI restriction enzyme sites (1220 bp containing gp120 V4, V5 and gp41 ectodomain n.t. 7250–8469 of pNL4-3) (Weiner et al., 1994). After restriction enzyme digestion and purification the NheI–BamHI fragments were ligated into pNL4-3, generating a series of molecular clones with the desired mutations.

Each molecular clone was transfected into 293T cells (10<sup>5</sup> cells/6-well culture plate). After 48 h, MT-2 cells (10<sup>6</sup> cells/well) were added and co-cultured with the 293T cells for an additional 24 h. When an extensive cytopathic effect was observed, the supernatants were harvested and stored at –80 °C for further use.

**Table 2**

<sup>a</sup> Anti-HIV-1 activity was determined using the amounts of p24 protein in the supernatants of the PHA-stimulated PBMC cultures using commercially available ELISA kit (Kodama et al., 2001). Bold indicates over 5-fold increase in EC<sub>50</sub> value compared to HIV-1<sub>WT</sub>.

<sup>b</sup> HIV-1<sub>NL4-3</sub> and HIV-1<sub>KT</sub> served as controls.

## 2.5. Determination of gp41 amino acid sequence

Nucleotide sequences of the clinical isolates were determined using an automated sequencer. Briefly, DNA was extracted from PBMCs infected with the clinical isolates, subjected to nested PCR for the gp41 coding region, and then directly sequenced as described previously (Nameki et al., 2005).

## 2.6. Measurement of circular dichroism (CD) spectra

N-HR peptides (N36, N36<sub>V38A</sub> or N36<sub>N43D</sub>) and C-HR peptides (C34 or SC34EK) were incubated at 37 °C for 30 min (the final concentration of both the N-HR peptide and the C-HR peptide were 10 μM in pH 7.4, 12 mM phosphate-buffered solution containing 50 mM NaCl). The wavelength-dependence of molar ellipticity [θ] was monitored at 25 °C as the average of eight scans, and the thermal stability was estimated by monitoring the change in the CD signal at 222 nm in a spectropolarimeter (Model J-710; Jasco, Tokyo, Japan) equipped with a thermoelectric temperature controller. The midpoint of thermal unfolding transition (melting temperature [T<sub>m</sub>]) of each complex was determined as described previously (Otaka et al., 2002). The percentages of α-helicity in 6-helix complexes were calculated by comparing the CD signal at 222 nm of N36/C34 or N36/SC34EK complexes in a spectropolarimeter.

## 2.7. Crystallization, data collection and refinement

Samples for crystallization were prepared by mixing solutions of N36 and SC34EK dissolved in 10 mM sodium acetate buffer at a concentration of 10 mg/mL. The mixture was incubated for 30 min at 37 °C, then was passed through a 22 μm filter. Crystallization was performed by the hanging drop vapor diffusion method at 4 °C. Droplets were prepared of equal amounts (2 μL) of reservoir solution and the peptide solution. Hexagonal prism crystals were obtained under the following conditions: 100 mM sodium acetate buffer (pH 4.0), 200 mM ammonium sulphate, 14% polyethylene glycol monomethyl ether 2000. After screening of

various cryo-conditions, the suitable condition was found to be the addition of 35% xylitol to the peptide solution and a slight increase in the amount of the precipitant (ca 14.5%). The obtained crystals were easily broken by direct transfer from the crystallization condition to the cryo-condition, but the transfer of the fragile crystals could be accomplished by gradual change in conditions using stepwise increase in the amount (0–35% in five steps) of the cryoprotectant.

Data were collected at a beamline BL38B1 of SPring-8. Collected data were processed using DENZO and SCALEPACK from the HKL2000 package (Otwinowski and Minor, 1997). A molecular replacement solution was found using AMoRe (Navaza, 2001), with a molecular model of the HIV-1 gp41 core structure (PDB code: 1AIK). Model refinements and reconstruction were performed using REFMAC5 (Murshudov et al., 1999) and XtalView (McRee, 1999). The final model was refined at a resolution of 2.1 Å, to a crystallographic R value of 0.213 and a free R value of 0.238. Detailed data collection and refinement statistics are summarized in Table 1. Atomic coordinates and structural factors have been deposited at the Protein Data Bank (PDB code: 2Z2T).

### 3. Results

#### 3.1. Anti-HIV-1 activity of SC34 and SC34EK

We examined the anti-HIV-1 activity of SC34 and SC34EK against not only HIV-1<sub>WT</sub> but also T-20- and/or C34-resistant clones observed in vitro. SC34 and especially SC34EK that has aligned EK modification more effectively suppress HIV-1 infection com-

pared to C34 and T-20 (Table 1). D36S/V38M substitutions in the gp41 region (HIV-1<sub>D36S/V38M</sub>), and a five amino acid (FNSTW) deletion in the V4 region of gp120 ( $\Delta$ V4) with L33S/N43K in the gp41 region (HIV-1 $\Delta$ V4/L33S/N43K) were isolated in vitro (Fikkert et al., 2002; Rimsky et al., 1998). L33S was also selected during C34-resistant induction in vitro (Armand-Ugon et al., 2003). C34 and its derivatives effectively inhibit entry of these clones into the host cell. In particular, SC34EK maintained strong activity even against V38E containing clones, such as HIV-1<sub>V38E/N42S</sub> (Armand-Ugon et al., 2003), which showed cross-resistance to T-20, C34 and SC34. Reduction of activities by SC34 and SC34EK was moderate in HIV-1 $\Delta$ FNSTW/L33S/N43K that showed high level resistance to T-20 and C34. Next, we examined the antiviral activities of C34 derivatives against clones containing major primary mutations V38A and N43D, which are mutations frequently observed in T-20 resistant variants in vivo (Cabrera et al., 2006; Derdeyn et al., 2001; Menzo et al., 2004; Poveda et al., 2004; Poveda et al., 2002; Xu et al., 2005) (Table 1). SC34 reduced its antiviral activities against HIV-1<sub>N43D</sub>, while SC34EK maintained its potent activity, indicating that when EK is bound with the complementary electrostatic interactions appropriately aligned SC34EK can effectively suppress the infection by various clones resistant to T-20 and C34 both in vitro and in vivo.

We further evaluated activities of SC34 and SC34EK against V3-substituted clones (Table 1). HIV-1<sub>V3-ADA</sub> uses mainly the CCR5 co-receptor for its entry into the host cells and has been reported to moderate T-20 resistance ( $\approx$ 10 fold), compared to the CXCR4 using strain of HIV-1, which shows higher susceptibility to fusion inhibitors (Reeves et al., 2002). As reported, the susceptibility of HIV-1<sub>V3-ADA</sub> to T-20 decreased, however, C34 and its derivatives maintained their activity against the same variant. Interestingly, in our experiments, HIV-1<sub>V3-SF162</sub>, HIV-1<sub>V3-CH1</sub> and HIV-1<sub>V3-CH2</sub> also showed comparable susceptibility to T-20. These results indicate that sequence variations in the V3 region do not always correlate with the observed T-20 susceptibility and are not involved in the resistance to C34 and its derivatives.

#### 3.2. Amino acid sequence

Amino acid sequences of clinical isolates are shown in Fig. 2b. One isolate, HIV-1<sub>KT</sub>, was obtained from a drug-naïve patient and the other three isolates (HIV-1<sub>411</sub>, HIV-1<sub>412</sub>, HIV-1<sub>A03</sub>) were obtained from heavily drug-experienced patients. None of the patients had received T-20 therapy. Amino acid sequences of the N-HR were highly conserved within all HIV-1 clinical isolates with some small variations. In contrast, the N36 region of the two HIV-2 strains, EHO and ROD, was identical in both HIV-2 isolates. We found some variations in the amino acid sequences of the HIV-2 strains we isolated, as compared with the sequences deposited in the GenBank (accession number; M15390 and X05291 for HIV-2<sub>ROD</sub>, and U272000 for HIV-2<sub>EHO</sub>). Namely, we identified two different amino acids in the isolated HIV-2<sub>ROD</sub>, V26L and

**Fig. 3.** Effect of FCS concentrations on anti-HIV-1 activity. Changes in the blue cell counts at various concentrations of FCS are shown. Blue cell counts at EC<sub>50</sub> value in 10% FCS concentration (black bar) were used and set as 100%. White, black, hatched, and striped bars correspond to 5, 10, 25, and 50% FCS, respectively. Inhibitors for reverse transcriptase, ddC and MKC-442, and for fusion, T-20 were used as controls.

I1571/M (mixture of I and M), and one variation in the amino acid sequence of HIV-2<sub>EHO</sub>, V45L. Except for I157M, other substitutions are observed in the majority of the HIV-2 strains, as reported in the HIV sequence database (Los Alamos National Laboratory: Los Alamos, NM, USA, <http://www.hiv.lanl.gov>). These substitutions might be introduced through different culture conditions, (e.g., host cells used for the propagation). We considered these substitutions as a polymorphism.

Sequence homology of the N36 region of the isolated HIV-1 strains was 31/36 (86%), including mutation D36G that is observed in the vast majority of HIV-1 strains (Kuiiken et al., 2001). In contrast, those of the C34 region were relatively heterogeneous, 24/34 (71%) for HIV-1 and 12/34 (35%) for HIV-2. Sequence identity of the T-20 region (residues 117–152) in the HIV-1 strains was also variable 27/36 (75%), while in the HIV-2 strains the sequence identity was 15/36 (42%). These results indicate that even highly conserved two helical extracellular domain of the gp41 can allow polymorphisms.

### 3.3. Efficacy of the peptides against clinical isolates

To evaluate preclinical efficacy, we examined the antiviral activity of C34, SC34 and SC34EK against clinical isolates (Table 2). Replication of HIV-1<sub>NL4-3</sub> and HIV-1<sub>KT</sub>, a drug-naïve strain, was suppressed by all compounds tested. C34 showed decreased activity against HIV-1<sub>IVR-A03</sub>, which was isolated from a heavily drug-exposed patient. SC34 also showed reduced susceptibility against three drug-experienced strains. However, it is difficult to conclude whether SC34 showed enhanced susceptibility against HIV-1<sub>KT</sub> or reduced susceptibility against drug resistant strains. In contrast, T-20 and SC34EK suppressed the replication of all isolates tested to similar extents in EC<sub>50</sub> values compared to HIV-1<sub>NL4-3</sub> (Table 2), indicating that SC34EK with appropriately aligned EK residues effectively suppresses the replication of the clinical 3 isolates.

### 3.4. Anti-HIV-2 activity

To confirm the target specificity, we examined antiviral activities of SC34 and SC34EK against two HIV-2 strains, EHO and ROD. Compared to HIV-1<sub>NL4-3</sub>, EHO and ROD contain 19 and 22 amino acid substitutions in the C34 region, respectively, and 15 amino acid substitutions in the N36 region, the anticipated site of binding of SC34 and SC34EK peptides (Fig. 2b). Like the parent peptide C34, both SC34 and SC34EK lost their potent activities (Table 3). Compared to HIV-1<sub>NL4-3</sub>, 6 out of 19 residues in the C34 region of HIV-2<sub>EHO</sub> and 7 out of 22 residues in the C34 region of HIV-2<sub>ROD</sub> are located at positions *a*, *d*, and *e* that directly interact with the N36 binding surface. These substitutions in the N36 and C34 region in HIV-2 may be responsible for reduced anti-HIV-2 activities of the peptides derived from HIV-1. At present, we cannot conclude which amino acid substitutions are directly involved in the reduced susceptibility of the HIV-2 strain to the treatment with the peptide fusion inhibitor, and/or whether other regions besides the N36 and C34 regions might influence peptide susceptibility. However, our results indicate that SC34 and SC34EK maintain similar target specificity to the parent peptide, C34.

### 3.5. Effect of fetal calf serum (FCS) on anti-HIV-1 activity

To estimate the stability of the peptides *in vivo*, binding level of SC34EK, to serum components, (e.g., albumin) was examined. In this experiment, the antiviral activity in the presence of relatively high concentrations of fetal calf serum (FCS) was determined (Baba et al., 1993) (Fig. 3). EC<sub>80</sub> values of the fusion inhibitors against HIV-1 replication *in vitro* were used. In the presence of 50% FCS, the activity of MKC-442 (1-EBU), a lipophilic non-nucleoside RT

inhibitor, was reduced 2.3-fold compared with 10% FCS as described previously (Baba et al., 1993). However, the activities of SC34, SC34EK and T-20 were little influenced by serum components. Among the three, SC34EK was the least affected by the concentration of FCS.

We further examined the stability of peptide inhibitors in freshly prepared human sera ( $n=3$ ). After 1 h incubation of peptides in human sera (final concentration of 200  $\mu$ M) at 37 °C, the anti-HIV-1 activity was examined using the MAGI assay. Comparable activities of all peptides tested were observed either with or without the incubation (data not shown). These results indicate that hydrophilic SC34EK likely retains its strong anti-HIV-1 activity *in vivo*, similarly to T-20, because of its low non-specific binding and protease cleavage in serum.

### 3.6. Peptide binding affinity

To clarify the mechanism of potent anti-HIV-1 activity observed with SC34EK, the binding affinity of SC34EK was evaluated by collecting the CD spectra using synthetic peptides. The CD spectra of equimolar mixtures of the N-HR and C-HR peptides showed spectrum minima at 208 and 222 nm, which indicate the presence of stable  $\alpha$ -helical conformations. All combinations of peptides showed similar spectra at 25 °C, indicating that these peptides contained the same  $\alpha$ -helicity (Fig. 4a), although the spectrum of C34 with N36 and N43D mutation (N36<sub>N43D</sub>) indicated only weak  $\alpha$ -helicity. These results indicate that N43D might reduce the stability of the conformation of the 6-helix bundle, thus decreasing the replication of HIV-1, whereas V38A does not. SC34EK formed stable 6-helix conformations with N36<sub>V38A</sub> and N36<sub>N43D</sub>. Under these experimental conditions, wavelength-dependent spectra were similar with the exception of the spectrum of the N36<sub>N43D</sub>/C34 complex. Thus, we analyzed thermal stabilities, defined as the midpoint of the thermal unfolding transition ( $T_m$ ) values, of the potential 6-helix bundles of N-HR and C-HR peptides.  $T_m$  of N36/C34 was found to be 52.0 °C, while that of N36<sub>V38A</sub>/C34 and N36<sub>N43D</sub>/C34 decreased to 44.5 and 34.0 °C, respectively (Fig. 3b). In contrast, thermal stabilities of N36<sub>V38A</sub>/SC34EK, N36<sub>N43D</sub>/SC34EK and N36/SC34EK were much higher, 60.5, 56.0 and 69.5 °C, respectively. Thus, binding affinity of SC34EK to N-HR was stronger compared to that of C34. Alternatively, at the physiological temperature of 37 °C, only 60 and 40% of the  $\alpha$ -helix content was observed in N36<sub>V38A</sub>/C34 and N36<sub>N43D</sub>/C34 mixtures, respectively, indicating that roughly half of C34 failed to form stably 6-helix bundle with the target N-HR harboring resistant mutations. Therefore, C34 reduces its anti-fusion activity exerted by dominant negative effect. In contrast, only 20% of the unfolded  $\alpha$ -helix content was observed in SC34EK with mutated N36, which indicated that at 37 °C, binding of SC34EK to mutated N36 was comparable to that of C34 with wild-type N36 (Fig. 4b). Moreover, physicochemical properties of N-HR and SC34EK complexes, defined by  $T_m$  value, correlated well with their ability to inhibit HIV-1 fusion (Fig. 4c). These results suggest that the stability of the 6-helix complex, as judged by the binding stability (affinity), is directly correlated with the anti-HIV-1 activity.

### 3.7. Crystal structure of the N36/SC34EK complex

The crystal structure of the complex between SC34EK and the N-HR representative peptide N36 was resolved to a resolution of 2.1 Å (Table 4). In the asymmetric unit, a 6-helix bundle consisting of a central helix bundle of three N36 peptides surrounded by three SC34EK peptides was found. This arrangement is similar in the core structure of gp41 (Chan et al., 1997). Structural superimposition of the original gp41 core and the N36/SC34EK complex showed a good match, with an RMSD value of 0.59 for main-chain atoms

**Fig. 4.** CD analysis of peptide complex between resistant variants of N36 and C34 or SC34EK. (a) Wavelength-dependent CD spectra of the complexes in solution. The spectrum minima at 208 and 222 nm indicated the presence of stable  $\alpha$ -helical conformations. (b) Thermal midpoint analysis was measured at 222 nm CD signal for the N and C peptide complexes. Final concentration of each peptide was 10 mM. The arrow indicates the physiological temperature of 37  $^{\circ}\text{C}$ . (c) The correlation between  $T_m$  (b) and  $\text{EC}_{50}$  values (Table 1). Colors of plots correspond to those in panels (a) and (b). Combination of N36<sub>N43D</sub> and C34 ( $\text{EC}_{50} > 100 \text{ nM}$ ) is excluded.

(Fig. 5a and b). Hydrophobic contacts between SC34EK and N36 with tryptophan rich domain (WRD) and leucine zipper were preserved for the original gp41 core. All introduced charged residues of the EK motif were directed toward the solvent (Fig. 5c). As a direct consequence of introducing the EK motifs, the ratio of surface area occupied by charged residues to the total surface area was increased from 35% in the original molecule to 60% in the N36/SC34EK complex. Importantly, it appeared that tight bonding, such as ion pairing or hydrogen bonding, was not present in the

side-chains of the residues of the EK motif. Electrostatic interaction may involve in constrained structure which provides the enhanced  $\alpha$ -helicity observed (Fig. 4). This structural analysis demonstrated that the interaction between N36 and SC34EK retained the ability to form the 6-helix bundle structure despite the substitution of more than one third of the residues (13/34) in the sequence of SC34EK.

#### 4. Discussion

In this study, we characterized a novel  $\alpha$ -helical peptide, SC34EK that effectively inhibits replication of HIV-1 strains resistant to T-20 and C34. The activity was specific to HIV-1 and little influenced by serum components. We demonstrate that the potent anti-HIV-1 activity of SC34EK is derived from its high affinity to the N-HR region by the CD analysis. Further, we reveal that SC34EK binds to its target, N-HR in identical manner that C34 does by the structure analysis.

The structural analysis of the N36/SC34EK complex clearly demonstrated that the interaction between SC34EK and N36 peptides was maintained by hydrophobic contacts and that the EK motif was directed toward the solvent. The introduction of the EK residues increased the proportion of accessible surface area occupied by charged residues. Although tight bonding was not observed, a continuous electrostatic potential between the EK residues may serve to stabilize the helix bundle. Such helix stabilization, which might occur on the surface of the HIV-1 virion between SC34EK and the N36 region of gp41, could result in the high anti-HIV-1 activity. In this regard, SC34EK, containing an aligned EK motif, showed more potent anti-HIV-1 activity compared to SC34, which has one misaligned EK motif (Fig. 2a). Increasing the hydrophilic surface area may prevent aggregation of SC34EK as compared to parental peptide C34. Therefore, SC34EK might distribute into the various organs in the body without being trapped and destroyed in the reticular systems or having its activity reduced by non-specific binding to proteins (e.g., albumin) (Fig. 3).

We further demonstrate that SC34EK specifically binds to the target, N-HR of HIV-1, since it only exerted weak activity to two

**Fig. 5.** Structure of the 6-helix bundle formed by N36 and SC34EK. (a and b) The gp41 core structure and N36/SC34EK complex are shown in red and blue, respectively. (c) Stick model representation of SC34EK. The stick model of SC34EK is shown, and three N36s in the core and two other surrounded SC34EK are represented in gray. SC34EK showed amphiphilic properties. The location of the N-terminal tryptophan rich domain (WRD) in SC34EK is indicated by a red circle. Original and introduced charged amino acids are indicated in green and blue, respectively.

HIV-2 strains that contain 15 amino acid substitutions in the N-HR compared to HIV-1 NL4-3 strain (Table 3 and Fig. 2b). These results suggest that to develop resistance to SC34EK, at least, certain mutations in not only the N-HR but also the C-HR are required to be introduced. This might delay emergence of resistant HIV-1 variants to SC34EK in vivo.

So far, some approaches for stabilizing  $\alpha$ -helix structures through the introduction of artificial amino acids were reported for HIV-1 fusion inhibitors T-20 (Judice et al., 1997) and C34 (Sia et al., 2002), including an example of an amino acid containing terminal olefin-derived side chains, designed as a substrate for the ring-closing olefin metathesis (Blackwell et al., 2001) and an example of a hydrocarbon-stapled peptides (Phelan et al., 1997). Walensky et al. (2004) applied a hydrocarbon-stapled modification to generate peptides that bind to the BH3 helical domain of Bcl-2, an anti-apoptotic protein, and demonstrated that a synthesized peptide mimic that binds to the BH3 domain activates apoptosis in leukemic cells. However, all peptides exerted only moderate activity in vivo, although they showed efficient binding to the target proteins in vitro (Blackwell et al., 2001; Judice et al., 1997; Sia et al., 2002; Walensky et al., 2004). It is likely that during the formation of the 6-helix bundle and the fusion process, gp41 changes its conformation drastically, suggesting that a flexible conformation of the peptide may be required to preserve actual inhibition. Compared with tethered, constrained peptides, EK modification that facilitates electrostatic stabilization displays such flexibility while exhibiting enhanced  $\alpha$ -helicity. Most recently, T290676, a 38 amino acid peptide, has been reported to suppress various fusion inhibitor-resistant strains of HIV-1 (Dwyer et al., 2007). Like SC34EK, T290676 is substituted with the charged and hydrophilic amino acids, glutamic acid (E) and arginine (R), at the solvent accessible site and shows potent anti-HIV-1 activity.

In conclusion, we have demonstrated that SC34EK selectively inhibits various HIV-1 strains, including T-20 resistant clones, through increased stability of the  $\alpha$ -helix. The sequence of the solvent accessible site of  $\alpha$ -helical peptides is replaceable and modifications of this sequence can regulate  $\alpha$ -helicity with target specificity. Therefore, our approach of introducing the EK motif in the  $\alpha$ -helical structure of the peptide inhibitor will help to generate future peptide inhibitors with high anti-HIV efficacy and potentially fewer adverse effects.

# Statistical Validation of the Relationships of Cancer Pain Relief With Various Factors Using Ordered Logistic Regression Analysis

Yuko Kanbayashi, MPH,\*†‡ Kousuke Okamoto, PhD,‡ Takanori Ogaru, PhD,‡§  
Toyoshi Hosokawa, MD, PhD,\* and Tatsuya Takagi, PhD†||¶

**Objective:** To clarify the relationships of cancer pain with various factors that prevent pain control statistically.

**Methods:** The participants were 71 terminal cancer patients admitted to the Department of Hematology/Oncology or Department of Gastroenterology/Hepatology, University Hospital, Kyoto Prefectural University of Medicine in whose pain control a pharmacist was involved as part of her clinical duties from January 2004 to November 2006. The effectiveness of pain control was evaluated using a 5-point verbal rating scale (0 = excellent, 1 = good, 2 = moderate, 3 = poor, and 4 = very poor) by interviewing the patients. As pain was rated using a graded scale and as many factors were involved in pain, analysis was performed using ordered logistic regression analysis. Moreover, prediction of an optimal model was performed by leave-one-out cross-validation to eliminate unnecessary variables. A program to perform leave-one-out cross-validation by ordered logistic regression analysis was prepared, independent variables used in the model were increased one by one, and calculation was performed in all combinations. Then, the optimal model was predicted by calculating the percent accuracy of predictions and Spearman rank correlation coefficient.

**Results:** Nausea [odds ratio (OR) = 1.948,  $P = 0.0232$ ], sex (OR = 2.322,  $P = 0.0030$ ), and bone metastasis (OR = 2.367,  $P = 0.0017$ ) remained as variables significantly correlated with pain when the number of independent variables was 5, and sex (OR = 2.167,  $P = 0.006$ ) and bone metastasis (OR = 2.093,  $P = 0.005$ ) remained when the number of variables was 6.

**Discussion:** The statistical identification of factors preventing pain control is considered to contribute to the establishment of an evidence-based approach to cancer pain relief.

**Key Words:** cancer pain, pain relief, palliative care, ordered logistic regression analysis, sex differences

Both pain treatment and palliative care have been areas farthest from evidence-based medicine (EBM), and many treatments in these fields have been performed on the basis of experience. EBM must also be established in pain relief by performing clinical studies on problems including pain assessment, effective use of drugs, and methods for the management of adverse effects.

Cancer pain is one of the major physical symptoms of cancer patients and the symptom that appears earliest among them, being reportedly observed in 30% to 40% of patients at the diagnosis of cancer and in 65% to 85% of patients with advanced cancer.<sup>1-3</sup> Cancer pain can be palliated by pain relief treatments of the World Health Organization in 85% to 95% of patients,<sup>4-9</sup> but pain control is still insufficient in some patients despite the administration of analgesics at sufficient doses. In the year 2002, the World Health Organization emphasized that "palliative care is an approach that improves the quality of life of patients and their families facing the problem associated with life-threatening illness, through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial, and spiritual."<sup>10</sup> In the year 1996, the American Society of Clinical Oncology also declared in the mission statement, "it is the oncologists' responsibility to care for their patients in a continuum that extends from the moment of diagnosis throughout the course of the illness. In addition to appropriate anticancer treatment, this includes symptom control and psychosocial support during all phases of care, including those during the last phase of life."<sup>11</sup>

Pain is nothing other than the report of "pain" by patients. However, pain is multifaceted, and Twycross<sup>12</sup> observed in his *Symptom Management in Advanced Cancer* that pain is easier to understand when it is regarded as total pain consisting of physical, psychological, social, and spiritual pain.

We performed this study to clarify the relationships of cancer pain relief with various factors that prevent pain control. The actual procedure used was ordered logistic regression analysis, as pain was evaluated by a graded scale and as multiple factors involved in pain must be evaluated simultaneously.

## PATIENTS AND METHODS

### Study Term and Participants

The participants were 71 terminal cancer patients admitted to the Department of Hematology/Oncology or Department of Gastroenterology/Hepatology, University Hospital, Kyoto Prefectural University of Medicine from

January 2004 to November 2006 in whose pain control a pharmacist was involved as part of her clinical duties. This study was performed with approval of the Ethical Review Boards of Kyoto Prefectural University of Medicine and Osaka University. Patients with whom no communication was possible throughout the hospitalization period were excluded from the participants. Opioids were administered for the control of cancer pain Table 1 shows the characteristics of the 71 patients.

**TABLE 1.** Patients Characteristics and Extracted Factors That May Affect Pain When Pain State (After) was Evaluated (n = 71)

	n (0/1)*	Mean ± SD	Range
Sex, female/male	24/47

\*The binary scales were female = 0 and male = 1 for sex, death = 0 and hospital change or discharge = 1 for outcome, and absent = 0 and present = 1 for others.

ALP indicates alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; γ-GT, γ-glutamyltransferase; NSAIDs, nonsteroidal anti-inflammatory drugs; P.O., peros.

### Evaluation of the State of Pain

Three kinds of the states of pain were evaluated by interviewing the patients using a 5-point verbal rating scale (VRS; 0 = excellent, 1 = good, 2 = moderate, 3 = poor, and 4 = very poor).

The dependent variable ( $Y = \text{after}$ ) was defined as the state of pain just before hospital discharge or the last opportunity of communication. The dependent variable ( $Y = \text{before}$ ) was defined as the state of pain on admission when pain control was poorest. The dependent variable ( $Y = \text{before-after}$ ), improvement factor.

### Statistical Analysis

#### Extraction of Variables

Variables were extracted in preparation for the analysis of multiple factors concerning pain control by regression analysis. The rating of pain on the VRS ( $Y = \text{after}$ ) was 0 in 28 patients, 1 in 29, 2 in 11, 3 in 3, and 4 in none; the rating of pain on the VRS ( $Y = \text{before}$ ) was 0 in 0 patients, 1 in 2, 2 in 12, 3 in 24, and 4 in 33; and improvement factor ( $Y = \text{before-after}$ ) was 0 in 0 patients, 1 in 8, 2 in 31, 3 in 28, and 4 in 4 (Table 2).

The minimum number of patients necessary to form a category of the dependent variable was 4 in the ordered logistic regression analysis used in this study and fewer patients were rated as 3 or 4 ( $Y = \text{after}$ ). Therefore,  $Y = \text{after}$  was recategorized into 3 levels: new level 0 indicates the original levels 0, new level 1 indicates the original levels 1, and new level 2 indicates the original levels 2, 3, and 4 (Table 3). Similarly, improvement factor ( $Y = \text{before-after}$ ) was recategorized into 3 levels: new level 1 indicates the original levels 0 and 1, new level 2 indicates the original levels 2, and new level 3 indicates the original levels 3 and 4 (Table 4).

**TABLE 2.** The Rating of Pain on the VRS (After, Before) and Improvement Factor (n = 71)

VRS	After Male	Before	Improvement
	(Female)	(Male, Female)	Factor (Male, Female)
0	28 (14)	0	0
1	29 (20)	2 (1)	8 (7)
2	11 (10)	12 (9)	31 (23)
3	3 (3)	24 (12)	28 (15)
4	0	33 (25)	4 (2)

VRS indicates verbal rating scale.

Table 1 shows the independent variables ( $X$ ) extracted from clinical records (retrospective survey). Binary scales were female = 0 and male = 1 for sex, death = 0 and hospital change/discharge = 1 for outcome, and no = 0 and yes = 1 for other factors.

## Analytical Procedure

### Ordered Logistic Regression Analysis (JMP 6; SAS Institute)

Ordered logistic regression analysis examines whether changes in variable  $Y$  (dependent variable) can be explained by changes in  $m$  variables ( $X_1, X_2, \dots, X_m$ ) (independent variables). For example, changes in the dependent variable  $Y$  are represented by the model:  $Y = b_0 + b_1X_1 + b_2X_2 + \dots + b_mX_m$  in multiple regression analysis and by the model:  $\log\{Y/(1-Y)\} = b_0 + b_1X_1 + b_2X_2 + \dots + b_mX_m$  in logistic regression analysis. In these models,  $b_0$  is a constant member in the equation and  $b_1, b_2, \dots, b_m$ , which represent the relationship between  $Y$  and  $X_i$  after elimination of the effects among the independent variables, are called partial regression coefficients. Regression analysis allows prediction concerning unknown data by constructing a model representing the phenomenon defined as the dependent variable on the basis of available data. Also, by evaluating the degree of the effect of each independent variable on the dependent variable according to the partial regression coefficient, it allows the analysis of factors (independent variables) that affect the dependent variable. In multiple regression analysis, dependent variables are continuous data, such as the concentration of a substance in blood, that are assumed to be linearly related to the independent variable. This concept of multiple regression can also be used to simultaneously examine the relationships among 2 or more categorical variables. However, the relationships among categorical variables are not simply linear, because the ranges of their values are finite. Therefore, generalized

**TABLE 3.** Dependent Variable ( $Y$ =After): Categorization of Data

Dependent Variable ( $Y$ )	VRS	No. Patients (71)
0	0	28
1	1	29
2	2, 3, 4	14

VRS indicates verbal rating scale.

**TABLE 4.** Dependent Variable ( $Y$ =Improvement Factor): Categorization of Data

Dependent Variable ( $Y$ )	Before-After	No. Patients (71)
1	0, 1	8
2	2	31
3	3, 4	32

linear models are used. If quantitative variables are included in independent variables, and if the dependent variable is a categorical variable, logistic regression analysis can be performed by applying a generalized linear model through converting the probability that the value of a categorical variable falls in a particular category ( $p$ ) into  $\log\{p/(1-p)\}$ , which can take infinitely small to infinitely large values (logit conversion). A logistic regression analysis can be used for binary variables such as pain (present or absent). If there are 3 or more categorical variables in this study, ordered logistic regression analysis can be used. Ordered logistical regression analysis was performed in this study to efficiently use the variables ( $Y$  = after, before, or improvement factor) extracted by means of a 5-point scale and because a large number of factors ( $X$  in Table 1) are involved in pain.

### Leave-one-out Cross-validation (LOOCV)

The ultimate objective of many multivariate analysis procedures is to construct a model for the prediction of related factors. In regression analysis, the relationships between the quantitative properties of samples of a variable (dependent variable) with those of 1 or more independent variables are established as a model. A common phenomenon that requires caution in all regression analysis procedures is that if the number of variables simultaneously considered in the model ( $m$ ) is excessively large, results that "overfit" the data may be obtained to reduce the predictive ability of the model. Also, if the number of samples of each variable is insufficient, the reliability of the model is impaired. Usually, the necessary number of samples ( $n$ ) is reported to be 5 to 10 times the number of variables ( $m$ ). After the construction of a model by applying multivariate analysis, the appropriateness of the model must be confirmed by checking, for example, whether overfitting, which was described above, has occurred.

Overfitting is a loss in the applicability of the model to data other than training data (data used for the preparation of a model) owing to overadjustment of the estimated values of the parameter to training data in the learning process of a categorization model using many parameters. To avoid overfitting, parameters must be selected using cross-validation, according to the precision of categorization of the test data prepared for the measurement of the predictive ability using data other than the training data.

Cross-validation means dividing data into 2 parts, preparing a model using one of them as training data, and examining the predictive ability of the model using the other part as test data. It is a technique to evaluate the number of variables used and predictive ability of the model equation itself. The procedure of LOOCV used in this study was as follows. First, 1 sample is temporarily excluded from the training data and a model is constructed

using the remaining training data. By employing this model, the dependent variable of the excluded sample is predicted, and the difference between the actual and predicted values of the dependent variable is recorded. Thereafter, the excluded sample is returned to the training data, another sample is excluded, a new model is constructed, and a new predicted value and its difference compared with the actual value are obtained. This process is repeated until all samples have been excluded once each. The optimal model can, thus, be selected from multiple models by comparison of the predictive ability.

Statistics and criteria used for this comparison are described as follows.

1. The percent accuracies of the model using test data by LOOCV.
2. Spearman rank correlation coefficients calculated according to the following expressions.

$$(R^2) = 1 - \frac{6 \sum d^2}{n^3 - n}$$

$d$  = the difference between each rank of corresponding values of  $x$  (= observed value) and  $y$  (= the predicted value), and  $n$  = the number of pairs of values.

## RESULTS

### Course of Analysis and Results

First, to accurately preserve the model, independent variables unnecessary for expressing the data as a model were excluded by calculating the percent accuracy. Independent variables were further screened by examining the multicollinearity, which occurs when there are correlations among independent variables and leads to the preparation of inappropriate models. As a result, 23 independent variables could be selected (Table 5) and the accuracy was 53/71.

Independent variables were further eliminated by estimating the optimal model on the basis of the evaluation of the predictive ability by LOOCV. A program to perform LOOCV by ordered logistic regression analysis was coded

by us, and the optimal model was predicted by calculating the percent accuracy of the prediction results and Spearman rank correlation coefficients between the actual dependent variable and prediction results.

In the process of reducing independent variables one at a time from the 23, the calculation program stopped when all variables had been applied. Therefore, we divided the 23 independent variables into 4 categories consisting of 6, 6, 6, and 5 variables and further eliminated them. The 4 categories were established by combining independent variables considered to be most closely interrelated and distributing independent variables considered to affect pain control among these categories markedly.<sup>12</sup> For example, category A includes characteristics of patients (eg, sex), B includes physical factors (eg, nausea), C includes psychosocial factors (eg, depression), and D includes laboratory test values (eg, bilirubin). Eliminated independent variables varied according to how they were categorized and the results were unreliable. Therefore, we decided to extract necessary independent variables rather than eliminate unnecessary ones. The predictive ability was calculated first in all models in which only 1 variable was used and by adding 1 variable to the models in all possible combinations. As a result, independent variables that always remained (sex, bone metastasis, and nausea) could be determined when the number of independent variables used in the models was increased to 3-6. The results are shown below.

### Procedure 1 [Y=After, Selection of Variables (X) When the Number of Variables was Increased to 5]

Among the combinations of 5 independent variables that gave the highest accuracy (41/71), Spearman rank correlation coefficient was highest (0.516) for the combination of sex, bone metastasis, nausea, sleep disorders, and cough. Ordered logistic regression analysis was performed using these independent variables. As a result, nausea, sex, and bone metastasis were significant (Table 6).

Spearman rank correlation coefficient was highest (0.538) for 8 combinations, all of which included sex, bone

TABLE 5. 23 Independent Variables that Remained After Elimination

Scale of Variable	Selected (23 Variables)	Eliminated (15 Variables)
Binary	Previous chemotherapy, sex, marriage, bone metastasis, outcome	Infection
	Physical symptoms: nausea, appetite, cough, fever	Physical symptoms: nausea, constipation, dyspnea
	Psychiatric symptoms: depression, sleep disorders, sleepiness	Psychiatric symptoms: delirium, malaise, confusion, and hallucination
	Concomitant medications: NSAIDs, steroids, analgesic adjuvants	
Continuous	Age	Opioid: daily dosage of morphine, fentanyl and oxycodone, log (daily dosage of morphine)
	Opioid: log (daily dosage of fentanyl and oxycodone)	Liver function: AST, ALP, $\gamma$ -GT
	Liver function: ALT, bilirubin	Other laboratory test items: platelet
	Kidney function: Serum creatinine	
	Other laboratory test items: total protein, hemoglobin	

ALP indicates alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase;  $\gamma$ -GT,  $\gamma$ -glutamyltransferase; NSAIDs, nonsteroidal anti-inflammatory drugs.

**TABLE 6.** Result of Procedure 1-1 ( $Y$ =After, Selected Variables When the Number of Variables was Increased to 5 on the Basis of the Percent Accuracy (Accuracy: 41/71, Spearman Rank Correlation Coefficient: 0.516))

Item	Estimated Value	Standard Error	$\chi^2$ Value	$P$	Odds Ratio	Confidence Interval of Odds Ratio	
						Lower 95%	Upper 95%
Sex	0.749	0.273	7.491	0.0061*	2.116	1.262	3.691

Cough	-0.123	0.273	0.204	0.6507	0.883	0.510	1.498

\* $P < 0.05$ .

metastasis, and nausea (total protein, fever, depression, cough, sleepiness, nonsteroidal anti-inflammatory drugs, and steroids were also included in some of them), and the accuracy was 39/71. As a result of ordered logistic regression analysis using these independent variables, nausea, sex, and bone metastasis were also significant (Table 7).

#### Procedure 2 [ $Y$ =After, Selection of Variables ( $X$ ) When the Number of Variables was Increased to 6]

Spearman's rank correlation coefficient was highest (0.545) for the combination consisting of sex, bone metastasis, nausea, alkaline phosphatase, outcome, constipation, and appetite, and the accuracy was 39/71. Ordered logistic regression analysis was performed using these independent variables. As a result, sex and bone metastasis were significant (Table 8).

#### Procedure 3 ( $Y$ =Improvement Factor)

Improvement factor ( $Y$  = before-after) was also evaluated. Similarly to the process performed when the final state of pain ( $Y$  = after) was selected as the dependent variable, the percent accuracy and multicollinearity were examined and variables were eliminated by LOOCV. As a result, sex, nausea, steroids, and log (daily dosage of morphine) (accuracy, 40/71; Spearman rank correlation coefficient, 0.328) were selected when the number of

variables was increased to 4. When ordered logistic regression analysis was performed using these variables as independent variables, only sex was significant (Table 9).

## DISCUSSION

The result of ordered logistic regression analysis revealed cancer pain to be significantly correlated with nausea, sex, and bone metastasis. As shown in Tables 6 to 8, the odds ratio (OR) indicated that pain is exacerbated when the patient is male and has nausea and bone metastasis. The data distribution of these 3 independent variables was 47:24 (male:female) for sex, 35:36 (present:absent) for nausea, and 26:45 (present:absent) for bone metastasis, showing no marked disparity between the categories.

Bone metastasis was significantly correlated with cancer pain. There has been no previous study in which the relationship between bone metastasis and cancer pain was statistically analyzed, but bone metastasis is widely perceived in palliative medicine as the greatest factor that impairs the quality of life.<sup>13-15</sup> External irradiation is a standard pain control treatment for bone metastasis, but internal radiotherapy is also considered in patients with multiple bone metastases to reduce their burden.<sup>16-19</sup> Recently, a report that bisphosphonate is also effective for pain relief has attracted attention, but the evidence is
