2.6. Flow cytometry

Cells were labeled with PE-Cy5-conjugated anti-CD4 antibody or PE-conjugated anti-CXCR4 antibody (Beckton Dickinson, San Jose, Calif.) for 30 min at 4 °C. Cells were washed once with PBS supplemented with 1% FBS and analyzed by FACS Aria (Beckton Dickinson). The GFP-positive cells were sorted using FACS Aria.

2.7. Monitoring HIV-1 replication

For HIV-1 infection, 1×10^5 cells were incubated at the room temperature with the HIV-1_{HXB2}-containing culture supernatant, which had approximately 1.0 ng of $p24^{CA}$, for approximately 30 min. The culture supernatants were collected at 4 d post-infection and subjected to ELISA to measure the $p24^{CA}$ antigen, using a Retro TEK p24 Antigen ELISA Kit according to the manufacturer's protocol (Zepto Metrix, Buffalo, NY). The signals were measured with an ELx808 microplate photometer (BIO-TEK®, Winooski, VT).

2.8. PCR analysis

The cellular DNA and RNA were extracted from cells infected with VSV-G-pseudotyped HIV-1 vector produced by using pNL-Luc plasmid, as described previously [17]. The Alu-LTR PCR and RT-PCR were performed as described previously [3,17] using the following primers: for the first Alu-LTR PCR reaction, 5'-AACTAGGGAACCCACTGCTTAAG-3' and 5'-TGCTGGGATTACAGGCGTGAG-3'; and for the second Alu-LTR PCR reaction, 5'-AACTAGGGAACCCACTGCTTAAG-3' and 5'-CTGCTAGAGATTTTCCACACTGAC-3'. For amplification of HIV-1 mRNA, 5′-ATGGAGCCAGTAGATCCTAGAC-3′ and 5′-CTATTCCTTCGGGCCTGTCGGG-3′ primers were used. For the control, we amplified beta-globin and cyclophilin A using the following primers: beta-globin, 5'-TATTGGTCTCCTTAAACCTGTCTTG-3' and 5'-CTGACACAACTGTGTTCACTAGC-3'; and cyclophilin A, 5′- CACCGCCACCATGGTCAACCCCACCGTGTTCTTCGAC-3′ and 5′- CCCGGGCCTCGAGCTTTCGAGTTGTCCACAGTCAGCAATGG-3′. The amplicons were separated in a 2% agarose gel, stained with ethidium bromide, and imaged with a Typhoon scanner (GE Healthcare Bio-Sciences).

2.9. Collection of virus-like particle

Tissue culture supernatants containing virus-like particles (VLP) were passed through nitrocellulose filters (0.45 μm, Millipore, Tokyo, Japan) and the virions were collected by centrifugation (Optima™ TL, TLA 100.3 rotor, 541 k × *g* for 1 h; Beckman Coulter, Miami, FL).

3. Results

3.1. Identification of SEC14L1a as a potential regulator of HIV-1 replication

We prepared MT-4 cells that constitutively express cDNA transduced by a lentiviral vector or an MLV-based retroviral vector (Fig. 1A). The cDNAs were derived from human peripheral blood mononuclear cells (PBL) and *Oryctolagus cuniculus* (European rabbit) kidney-derived cell line RK13 cells. MT-4 cells transduced with cDNA were collected by FACS sorter using the green fluorescence as a marker since viral vectors encoded the GFP expression cassette. Then, cells were infected with HIV-1. Surviving cells were propagated and the genomic DNA was extracted to recover the transduced cDNA by PCR as previously described [3]. We isolated two clones encoding the carboxy terminal domain (CTD) of SEC14L1a (Gene ID 6397, Fig. 1B and C); one from the PBL cDNA library (1/65 independent clones, 1.5%), and one from the RK13 cDNA library (1/42 independent clones, 2.4%). The fact that the SEC14L1a CTD was successfully identified from two independent cDNA libraries strongly suggests that it is a negative regulator of HIV-1 replication. It is important to note that previous genome-wide screenings for HIV-1 regulators have not identified SEC14L1a CTD. This clearly suggests that our T cell-based cDNA screening system is unique, and should be able to complement the other genome-wide screening systems.

SEC14L1a belongs to the widely-expressed SEC14-superfamily that is involved in membrane trafficking and phospholipid metabolism [18–21]. The function of SEC14L1a is not well understood. The C-terminus of SEC14L1a encodes a Golgi dynamics (GOLD) domain (amino acids (aa) 523–674; Fig. 1C) that mediates the protein-protein interaction possibly involved in the maintenance of Golgi apparatus function and vesicular trafficking [22]. The only reported biological activity of SEC14L1a is to interact with cholinergic receptors AchT and CHT1 [23]. The GOLD domain is responsible for the physical interaction between SEC14L1a and cholinergic receptors. However, the functional significance of these interactions remains to be clarified. The conserved SEC14 domain directly interacts with lipid molecules [17–21]. However, the lipid ligand of SEC14L1a (aa 319–490, Fig. 1C) has yet to be identified.

3.2. Construction of expression vectors for SEC14L1a derivatives

The longest SEC14L1a cDNA recovered from the PBL cDNA library spanned nucleotides (nt) 2045–2492 of SEC14L1a mRNA (NM_003003.3), covering the CTD of the SEC14L1a open reading frame (ORF; Fig. 1B). We detected a potential translational start codon at nt 2188-2190 within the GOLD domain (asterisk, Fig. 1B). We speculated that the isolated cDNA might have expressed the carboxy half of the GOLD domain (aa 641–715) in MT-4 cells, leading to the inhibition of HIV-1 replication.

To test this, we constructed an expression plasmid for FLAG-tagged CTD (aa 642-715) fused to the carboxy terminus of GFP (CTD1; Fig. 1C). We also constructed GFP fusion proteins spanning the GOLD domain (CTD2, aa 493–715) or the full-length SEC14L1a (FL; Fig. 1C). Expression of these proteins was verified by Western blotting of transient transfected 293T cells (Fig. 1D). The confocal microscopy analysis indicated that the FL localized mainly in the cytoplasm, with some accumulation in the perinuclear regions (Fig. 1E), consistent with a previous report [23]. CTD1 was distributed in the cytoplasm and the nucleus, with a slight preference for the cytoplasm. CTD2 was evenly distributed to the nucleus and cytoplasm. When MT-4 cells constitutively expressing FL, CTD1, and CTD2 were analyzed, the subcellular distribution was less clear, due to the small cytoplasm (Fig. 1F). However, FL was distributed evenly to the nucleus and cytoplasm in MT-4 cells. In contrast, CTD1 was excluded from the nucleus in MT-4 cells (Fig. 1F). The distribution of CTD2 in MT-4 cells was similar to that in 293T cells (Fig. 1F). The differences of protein distribution in two cell types may be caused by the cell type-dependent regulation of protein trafficking and/or the effect of protein expression levels.

3.3. Verification of anti-HIV-1 activity associated with SEC14L1a CTD1

We introduced FL, CTD1, or CTD2 into MT-4 cells using the MLV vector, and isolated cells constitutively expressing FL, CTD1, or CTD2. Expression of SEC14L1a derivatives in MT-4 cells was verified by Western blotting (Fig. 2A). FL expression was verified by immuno-precipitation assay (Fig. 2A). The detection of FL by Western blotting was inefficient considering the fact that all the SEC14L1a derivatives are GFP-tagged, and the GFP intensity of FL-expressing MT-4 cells was not lower than that of CTD1-expressing

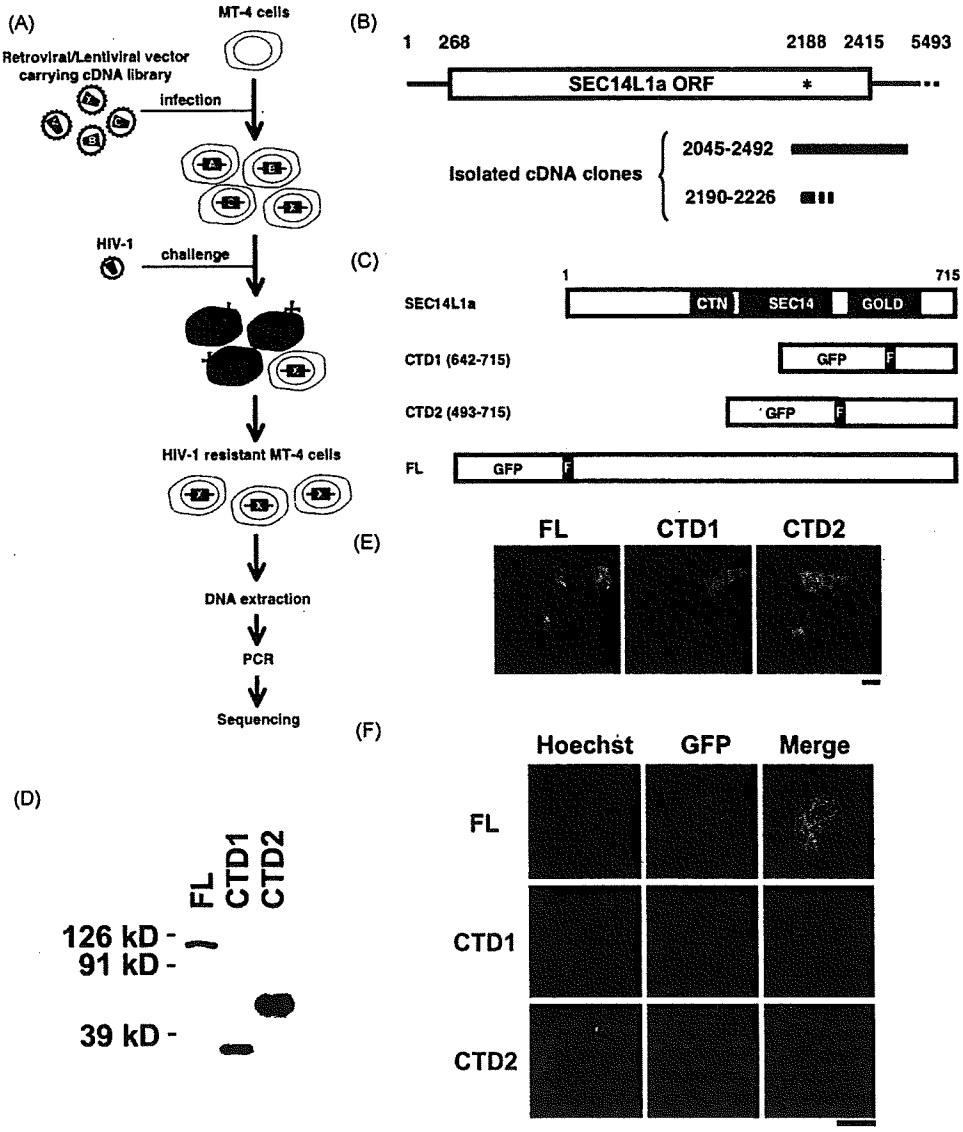

Fig. 1. Identification of SEC14L1a CTD as a potential regulator of HIV-1 replication. (A) The experimental strategy used to screen a cDNA library for genes rendering cells resistant to HIV-1. MT-4 cells were infected with a retroviral or lentiviral vector carrying cDNA libraries and were challenged with wild-type HIV-1_{HXB2}. The HIV-1-infected cells (gray with cross) quickly undergo cell death. The surviving cells were propagated, collected, and the transduced cDNA labeled X was determined. (B) Schematic representation of SEC14L1a mRNA (NM_00303.3) and the isolated gene fragments. The open reading frame (ORF) is assigned from nucleotides (nt) 268 to 2415. The potential internal translational initiation codon is marked with an asterisk. (C) Schematic representation of the SEC14L1a protein (NP_002994). SEC14L1a has a CRAL-TRIO-N domain (CTN, amino acids 241–313), a SEC14p-like lipid-binding domain (SEC14, amino acids 319–490), and a Golgi dynamics domain (GOLD, amino acids 523–674). The cloned fragments (CTD1 and CTD2) and full-length (FL) gene were tagged with a FLAG epitope (indicated with an "F") on their N-termini, and fused to the C-terminus of GFP. (D) Verification of FL, CTD1, and CTD2 expression in 293T cells by Western blotting using anti-FLAG antibody. (E) Confocal microscopy images of 293T cells expressing FL, CTD1, or CTD2. The green signal represents GFP fluorescence. Magnification, 630×; scale bar, 10 μm. (F) Confocal microscopy images of MT-4 cells constitutively expressing FL, CTD1, or CTD2. The blue signal represents the Hoechst-stained nucleus, and green represents GFP fluorescence. Magnification, 630×; scale bar, 5 μm.

cells (Fig. 1F). The MLV vector expressing GFP alone was used as a control. The cell proliferation, morphology, and cell surface levels of HIV-1 receptors were unaltered by any of the SEC14L1a derivatives (Fig. 1F, 2B, and data not shown). HIV-1 replication was tested in these cells. The level of HIV-1 replication was significantly inhibited in CTD1- and CTD2-expressing cells (69.1% and 69.8% on the average from seven independent experiments, respectively, $P < 0.05$, two-tailed Student's t-test), but was hardly inhibited in FL-expressing cells (86.4%, not statistically significant; Fig. 2C). This observation was reproducible in independently established MT-4 cells and SupT1 cells (data not shown). These data verified the original screening results, and suggest that the C-terminal half of GOLD domain of SEC14L1a serves as an inhibitor of HIV-1 replication. In contrast, it is suggested that FL is not a potent negative regulator of HIV-1 replication.

3.4. SEC14L1a CTD1 and CTD2 target the late phase of the HIV-1 life cycle

We analyzed the viral entry and production phases to determine which step of the HIV-1 life cycle CTD1 and CTD2 target.

The Alu-LTR PCR assay was performed to examine the effect of SEC14L1a derivatives on the viral entry phase. The MT-4 cells stably expressing GFP, FL, CTD1, or CTD2 were infected with VSV-

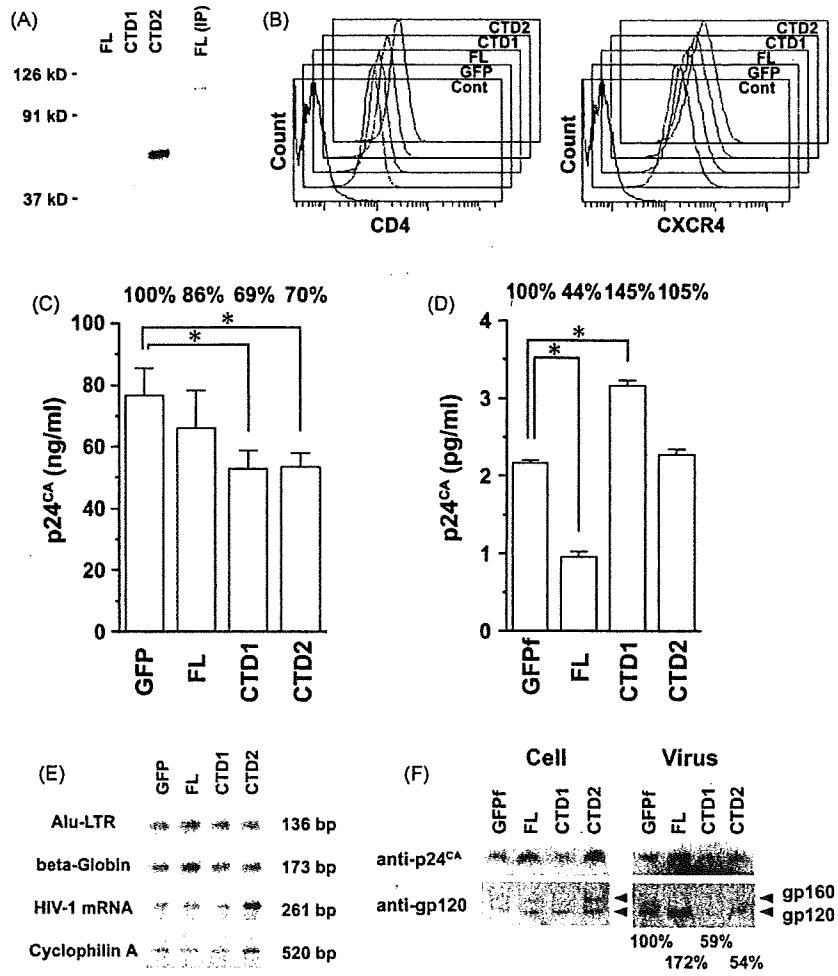

Fig. 2. Functional characterization of the SEC14L1a derivatives. (A) Detection of stable expression of FL, CTD1, and CTD2 in MT-4 cells by Western blotting using anti-FLAG antibody. FL was detected by the immunoprecipitation (IP) assay using agarose beads conjugated with anti-FLAG antibody. The flow cytometric analysis of the cell surface expression of HIV-1 receptors CD4 and CXCR4 in MT-4 cells stably expressing GFP, FL, CTD1, and CTD2. (C) Constitutive expression of CTD1 and CTD2 limited the replication of HIV-1 in MT-4 cells. The concentration of viral $p24^{CA}$ antigen in the culture supernatant was measured at 4 d post-infection. The results represent the average of seven independent experiments ± the standard error of the mean. The reduction of viral $p24^{CA}$ concentration relative to GFP was shown on the top. Asterisks indicate the statistical significance compared to GFP ($P < 0.05$ by two-tailed Student's *t*-test). (D) The PCR-based assay to examine the effect of SEC14L1a derivatives on the early phase of viral life cycle (top two panels) and the transcription from LTR promoter (bottom two panels). The HIV-1 entry efficiency was examined by Alu-LTR PCR. Beta globin was used as an internal control. The HIV-1 transcription efficiency was examined by RT-PCR targeting spliced viral mRNA. Cyclophilin A was used as a control. The expected length of each PCR amplicon was indicated. (E) The effect of SEC14L1a derivatives on the HIV-1 production. The 293T cells grown in a well of a 6-well plate were transfected with 200 ng of HIV-1 proviral DNA and 2 μg of expression vector for GFPf, FL, CTD1, or CTD2. The culture supernatant was recovered at 2 d post-transfection and the $p24^{CA}$ concentration was measured. The representative data from five independent experiments was shown. The results indicate the average ± the standard deviation. The relative $p24^{CA}$ concentration compared to GFPf was shown on the top. Asterisks indicate the statistical significance compared to GFPf ($P < 0.001$ by two-tailed Student's *t*-test). The *Env* incorporation onto the virus-like particles (VLP) produced by 293T cells expressing SEC14L1a derivatives. The 293T cells grown in a well of a 6-well plate were transfected with 1 μg of *gag-pol* (pCMVR8.91) and *Env* (pIIIex) expression vectors along with 2 μg of expression vector for GFPf, FL, CTD1, or CTD2. The cell lysates (Cell) and VLP fractions (Virus) were subjected to Western blot analysis detecting gp120 and $p24^{CA}$ harvested at 2 d post-transfection. The *Env* incorporation levels normalized to $p24^{CA}$ relative to GFPf were shown at the bottom.

G-pseudotyped HIV-1 vector, and the cellular genomic DNA was recovered at 4 d post-infection. The amount of Alu-LTR PCR products from FL-, CTD1-, or CTD2-expressing MT-4 cells was almost equal to that from GFP-expressing cells, suggesting that the early phase of the viral life cycle is not inhibited by any of the SEC14L1a derivatives (Fig. 2D). To examine the viral production phase, we examined the LTR-driven viral gene transcription by RT-PCR. Cellular RNA was extracted from the same MT-4 cells infected with VSV-G-pseudotyped HIV-1 vector, and RT-PCR was conducted to amplify LTR promoter-driven spliced HIV-1 mRNA. The amount of viral RNA expressed in FL-, CTD1-, or CTD2-expressing cells was not lower than that in GFP-expressing cells when the levels of the internal control was taken into account (Fig. 2D). Given that the similar number of viral genome was integrated as indicated by the Alu-LTR PCR, these data suggest that viral transcription is not inhibited by any of the SEC14L1a derivatives, and that the action point of CTD1 and CTD2 should be at post-transcriptional levels of the viral production phase.

Next, the FL, CTD1, or CTD2 expression vector was co-transfected with HIV-1 proviral DNA into 293T cells, and viral production was quantified by $p24^{CA}$ ELISA. The FLAG-tagged GFP (GFPf) was used as a control hereafter. We found that the FL expression significantly reduced the production of HIV-1 (44.2%, $P < 0.001$, two-tailed Student's *t*-test) compared to the GFPf control (Fig. 2E). In contrast, the CTD1 enhanced the production of HIV-1 (145.9%, $P < 0.001$, two-tailed Student's *t*-test; Fig. 2E). However, CTD2 did not measurably affect the HIV-1 production (105.1%, not statistically significant; Fig. 2E). As the ELISA assay examines the effect

Please cite this article in press as: Urano E, et al. T cell-based functional cDNA library screening identified SEC14-like 1a carboxy-terminal domain as a negative regulator of human immunodeficiency virus replication. Vaccine (2009), doi:10.1016/j.vaccine.2009.07.084

of CTDs on *Gag* functions, we next tested the functional interaction between CTDs and *Env*. The *Env* incorporation onto the virion was examined by tripartite-transfection of expression vectors for *Env*, *gag-pol*, and SEC14L1a derivatives into 293T cells, and the VLP was collected by centrifugation. The immunoblotting against gp120 was performed on the cell lysate and the VLP fraction. The cellular *Env* and *Gag* expressions were not detectably affected by any of the SEC14L1a derivatives (Fig. 2F, left panel). The *Env* incorporation onto the VLP was slightly enhanced by FL (157%; Fig. 2F, right panel). In contrast, the VLP produced from CTD1- or CTD2-expressing cells incorporated substantially fewer *Env* than those from GFPf-expressing cells (59% or 54%, respectively; Fig. 2F, right panel). These data were reproducible in independently performed experiments. The densitometric analysis of Western blot image showed that the average ± the standard error of the mean of Env incorporation onto the virion was 129.7 ± 39.9%, 54.8 ± 24.7%, and 25.5 ± 10.3% for FL, CTD1, and CTD2 compared to GFPf, respectively (3–4 independent experiments). The *Env*-mediated cell-to-cell fusion assay indicated that SEC14L1a derivatives did not limit the cell surface targeting and function of *Env* (data not shown). In addition, the *Gag* processing in virion was unaffected by any of the SEC14L1a derivatives (data not shown). Collectively, these data suggest that the HIV-1 replication is inhibited by CTD1 and CTD2 due to the inefficient *Env* incorporation onto the virion. To test this possibility, we infected fresh MT-4 cells with the equal amount of HIV-1 propagated in CTD1- or CTD2-expressing MT-4 cells (1–2 ng $p24^{CA}$), and the viral replication was monitored at 3–4 days post-infection by measuring the $p24^{CA}$ concentration. The infectivity of HIV-1 propagated in CTD1- or CTD2-expressing cells was attenuated to 83.1 ± 17.9% or 82.4 ± 5.5% relative to the virus recovered from GFP-expressing cells, respectively (the average ± the standard error of the mean of 3 independent experiments). Altogether, these data suggest that the inhibition of HIV-1 replication by CTD1 and CTD2 is attributed to the attenuation of viral infectivity by lowering the *Env* incorporation onto the virion.

4. Discussion

In the present study, we provide the first evidence that the C-terminal fragment of SEC14L1a functions as an inhibitor of HIV-1 replication. The advantage of this system is that, since MT-4 cells are stably transduced with a cDNA library, the anti-HIV-1 function of a candidate gene is not due to a perturbed cell physiology. This system has been successful in identifying CD14, CD63, and Brd4-CTD as regulators of HIV-1 replication [1,3,4], and more candidates are being analyzed. Among the candidates, SEC14L1a CTD appeared to be one of the relatively modest inhibitors of HIV-1 replication. However, of note, the SEC14L1a derivatives have not been identified in other genetic screening systems. These facts point that our T cell-based system is sensitive in detecting the modest anti-HIV-1 activity of a gene, and is a unique tool in the pursuit of HIV-1 regulatory factors to complete the HIV-1-host interactome.

SEC14L1a may affect the Golgi-mediated vesicular trafficking since SEC14L1a lowers the cell surface levels of cholinergic transporters [23]. However, we do not have any data to suggest that SEC14L1a and its derivatives affect the cell surface targeting of membrane proteins including CD4, CXCR4 and *Env*. These data suggest that SEC14L1a's effect on cholinergic receptor expression is specific, and that the CTD's ability to inhibit HIV-1 replication is independent from SEC14L1a's regulatory functions on vesicular trafficking. The action point of CTD1 and CTD2 was shown to be the late phase of the viral life cycle. Given that CTD1 and CTD2 did not inhibit the biogenesis and the cell surface targeting of *Gag* and *Env*, the major mechanism of CTD1 and CTD2 to inhibit HIV-1 replication was to reduce the infectivity of HIV-1 by limiting the *Env* incorporation onto the virion. Consistent with this idea, the viral infectivity of virions produced in CTDs-expressing cells was attenuated. Then, how do CTDs block the *Env* incorporation onto the virion? We detected a weak interaction between *Gag* and CTD1 or CTD2 by immuno-coprecipitation analysis. Thus, we speculate that the interaction between *Env* and *Gag* at the plasma membrane is interfered by *Gag*-CTDs interaction, resulting in the reduction of *Env* incorporation onto the virion.

The CTD1 was an inhibitor of HIV-1 replication. While the CTD1 negatively affected the *Env* incorporation onto the virion, it positively affected the HIV-1 production. These observations may be seemingly controversial. However, the SEC14L1a derivatives' effect on HIV-1 replication is a summation of their effects of on each step of the viral life cycle. Therefore, it is conceivable that CTD1 can serve as a negative regulator of HIV-1 replication as well as a positive and negative factor on distinct steps of the viral life cycle. These seemingly controversial findings may be in part due to the cells in which the biological functions of SEC14L1a derivatives were examined. The effect of SEC14L1a derivatives on HIV-1 replication was investigated in MT-4 cells, whereas those on the HIV-1 production and *Env* incorporation onto the virion were examined in 293T cells. Although the basic biological features are largely shared among different cell types, it is possible that the SEC14L1a derivatives may function slightly differently in MT-4 cells from 293T cells given that the intracellular distribution of SEC14L1a derivatives in MT-4 cells was not identical to that in 293T cells (Fig. 1E and 1F).

Elucidating the molecular mechanism underlying CTDs' activity not only provides a hint to understand how the HIV-1 virion actively uptakes *Env* through the *Gag-Env* interaction, but also leads to the development of a novel anti-retroviral drug that lowers the infectivity of the virus by preventing *Env* incorporation onto the virion. This is the strength of our T cell-based assay since CTDs inhibit HIV-1 replication specifically. In the previous study, we proposed that a small portion of Brd4 may serve as a therapeutic molecular target for HIV-1 infection, since the constitutive expression of Brd4-CTD limited HIV-1 replication specifically [3], akin to the SEC14L1a CTDs. However, it remains to be examined whether the SEC14L1a and Brd4 derivatives inhibit HIV-1 replication in primary HIV-1 target cells.

The genome-wide screening has potential caveats, including a cDNA bias and a cell line bias. A cDNA library is not a perfect representation of mRNA expressed in the cells from which the library is constructed. For example, the longer the mRNA, the less efficiently the full-length cDNA is synthesized. In fact, we isolated Brd4-CTD from the PBL cDNA library as a potent inhibitor of HIV-1 replication [3]. However, although Brd4 (approximately 5000 nt mRNA in length) is expressed in MT-4 cells, we were unable to recover Brd4-CTD from the MT-4 cDNA library [3]. This clearly demonstrates the cDNA bias in the genetic screening. A cDNA library derived from non-T cells does not contain genes specifically expressed in T cells. Thus, we have to explore many more cDNA libraries to completely cover the genetic diversity of human cells. The cDNA libraries isolated from long-term non-progressors of HIV-1-seropositive individuals or from elite controllers might be of particular interest, considering that a dominant innate HIV-1 resistance gene, such as CCR5 delta 32, may partly account for the slow progression of AIDS. Similarly, use of a particular cell line and/or virus strain may bias the results. MT-4 cells are positive for HTLV-1, and are able to support robust HIV-1 replication. MT-4 cells do not express CCR5, and are unable to support R5-tropic HIV-1 strains. What if other T cell lines and R5-tropic viral strains are used? What if we assay the same cDNA library in TZM-bl cells? We plan to address these issues in the future studies.

In conclusion, genome-wide genetic screening is a powerful tool for identifying the regulatory factors of HIV-1 replication and innate HIV-1 resistance factors that limit HIV-1 infection and AIDS progression. The HIV-1-host interactome should also reveal poten-

Please cite this article in press as: Urano E, et al. T cell-based functional cDNA library screening identified SEC14-like 1 a carboxy-terminal domain as a negative regulator of human immunodeficiency virus replication. Vaccine (2009), doi:10.1016/j.vaccine.2009.07.084

tial therapeutic molecular targets that may be used to develop novel anti-AIDS drugs to tackle the emerging drug resistant viruses. However, the fact that different experimental systems often yield non-overlapping candidates suggests that we have to explore more experimental systems to fully understand the HIV-1-host interactome. Our T cell-based system provides an alternative tool for identifying novel HIV-1 regulatory factors, and should help us understand the HIV-1-host interaction in more detail.
