

$$1 = \frac{\text{Cov}(\ln c_{hst}^N, \ln c_{hst}^D)}{\text{Var}(\ln c_{hst}^N)} + \frac{\text{Cov}(\ln c_{hst}^N, \ln d_{hst}^E)}{\text{Var}(\ln c_{hst}^N)} + \frac{\text{Cov}(\ln c_{hst}^N, \ln e_{hst}^N)}{\text{Var}(\ln c_{hst}^N)}$$

$$= b_1 (\ln c_{hst}^N, \ln c_{hst}^D) + b_2 (\ln c_{hst}^N, \ln d_{hst}^E) + b_3 (\ln c_{hst}^N, \ln e_{hst}^N)$$

Results

There used to be wide geographical variance of the aged hospitalization cost per capita (C/N)

The large variance is mostly explained by correlation of (C/N) with (E/N)

E/N is per capita hospitalization admission

Higher (C/N) is associated with higher (E/N)

Higher (C/N) is associated with lower (C/D)

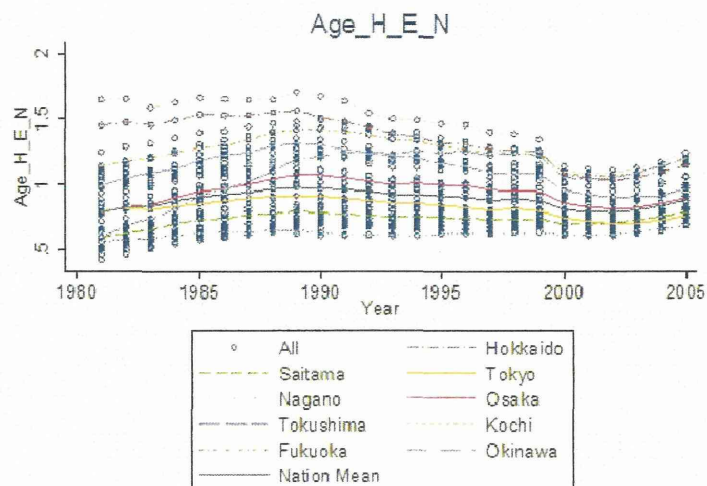

These two effects have become much smaller lately especially after the introduction of the long-term care insurance in 2000.

After the introduction, there is the trend of wider variance of C/N again

Aged Hospitalization Real Cost per Population (C/N)

Aged Hospitalization Events per Population (E/N)

Interpretations

In Japan, there was the large geographical variance in medical cost of the aged hospitalization, which has decreased through the 1980-2000 period.

Decreased variance of C/N is caused by decreased covariance of (C/N) and (E/N).

It might be related to medical resources per capita.

Introduction of long term-care insurance has significantly reduced variance, which trend is somewhat reversed after 2000.

Estimation

$$y_{ht} = \ln q_{ht} - \overline{(\ln q_t)}$$

$$y_{ht} = e^{-\delta_i} \cdot y_{ht-1} + \sum_i^K \beta_i X_{ht}^i + \sum_{j=1}^H \gamma_j D_j + \sum_{l=1}^M \tau_l T_l + u_{ht}$$

$$y_{ht} - y_{h,t-T} = e^{-\delta} \cdot (y_{ht-1} - y_{h,t-1-T}) + \sum_i^K \beta_i (X_{ht}^i - X_{h,t-1-T}^i) + \sum_{l=1}^M \tau_l T_l + (u_{ht} - u_{h,t-T})$$

Estimation Results

1. Too high speed of convergence
Coefficients of the lagged dependent variables 0.40-0.50
With the average "conditions", the speed of convergence exceeds 0.25 per year (overestimation)
2. C/D (cost per day) is negatively related with D/E (days per event) or with E/N(events per population)
3. The larger GDP increases C/D, E/N not D/E
Beds per population increases D/E
Physicians per population has no effects
Nurses per population increases C/D
Aged home capacity decreased D/E while increases E/N

Limitations

Data is 47 prefectures level data and not individual patient data
 This is required to use data for social capital endowment and to
 examine conversion across regions.

We do find conversion for "Aged, Inpatient"
 But we still far from accounting for the reason behind.

We initially expected that social capital endowment of physicians,
 nurses, and beds account for the growth of medical cost and its
 conversion.

What we find is a structural change between 1981-1991 and 1992-
 2000. Conversion is not driven by market but by political initiatives.
 We need to know the different roles of regional governments.

Tentative Results

A1: Increase in medical cost is due to “population growth” in Aged Inpatient and outpatient
“cost per day”
while “days per person” has declined

A2: Extremely large estimates of convergence
speed, 25 percent a year

A3: Estimation and decomposition have different
results.

Tentative Results

A1: Increase in medical cost is due to “population growth” in Aged Inpatient and outpatient
“cost per day”
while “days per person” has declined

A2: Extremely large estimates of convergence
speed, 25 percent a year

A3: Estimation and decomposition have different
results.

Limitations

Estimations of the conditional convergence tend to overestimate convergence speed

Decomposition and estimation have the different results.

Social overhead capital are related to medical cost in more complicated manner

Geographical Variation and Convergence of Medical Cost in Japan

(2012)

Summary

[Background] Over half century Japan has adopted a nationwide universal health insurance plan and has successfully achieved high health outcome in longevity throughout the country. At the same time, Japan has exhibited wide geographical variances in endowment of medical resources (physicians, nurses, beds etc.) as well as medical cost in terms of cost/person (C/N). Based on assumptions of the “suppliers induced demand”, the Japanese government has introduced regulation on new entry of hospitals and has reduced the number of patient beds to contain medical expenditure. Also the government has established the “long-term care insurance plan” in 2000, which shifts the care for the aged from hospitalization to long-term care services.

Although there are many empirical researches on geographical variance as surveyed in IHEP (2007), there are common shortcomings. First, they mostly rely on cross-section data or with data of short time-periods. Second, most studies investigate the effects of explanatory variables in ad hoc manner without theoretical framework. As a result, they fail to identify the sources of geographical variance and pattern of convergence.

[Method and Data] This study investigates the pattern and the sources of geographical variance and convergence of medical cost. This study uses medical cost data of the “Municipal Health Insurance Plan” and health related data of 47 prefectures in 1981-2005 by pooling time-series and 47 cross-section data. We distinguish three types of medical services “hospitalization”, “outpatient”, and “dental” services for the “general” and the “aged” population. This study uses a method to identify the source of convergence of geographical variance of income as in Asrdubali, Sorensen, and Yosha (1996) and Nakakugi and Fujiki (2005). Using a relationship that “Cost per capita (C/N)” as the product of “cost per day (C/D)”, “days per event (D/E)” and “events per population (E/N)”, we can analyze the pattern and sources of variance and convergence. Also we estimate speed of convergence in an absolute and conditional convergence sense as in Barro and Sala-i-Martin (1992).

[Results] Degrees of geographical variance has differed across types of medical services. There is large variance of “cost per capita (C/N)” for the “aged hospitalization” in the early 1980s, which has decreased rapidly through the period. This is caused by the reduced variance of “events per population (E/N)” which in turn is related to “beds per population. (Beds/N)”. The suppliers induced demand holds for the aged hospitalization. The government policy Introduction of the long-term care insurance plan in 2000 shifted aged hospitalization to long-term care and had induced convergence of C/N for the aged hospitalization. Variance of cost per day (C/D) for aged hospitalization and aged out patient services. We also find fairly large speed of convergence for the aged hospitalization.

[Conclusions] Although geographical variance was a serious policy concern in the 1980s, it should be limited to that of aged hospitalization. And it had declined significantly over the periods by limiting supply of patient beds. Introduction of long-term care in 2000 also helps convergence. We find our method and data identify patterns and sources of variance and convergence.

Key words: medical, health, geography, convergence JEL: J14, J18, O49

1. Introduction

Although Japan has achieved high longevity across regions, there are significant differences in health capital, medical services, and medical cost. Geographical variation of medical sector within the country is widely known and there are numerous studies on geographical variations (Cutler David and Louise Sheiner (1999)¹, Wennberg, John E. Elliott S. Fisher, and Jonathan S. Skinner (2002)²). As to Japan, a number of studies deal with the same problem. There are two types of studies, one is to use individual data on medical claims, and the other is to use aggregate data for each region. As to the latter, most studies use 47 “prefecture” data (IHEP, 2007)³. Although it is common to utilize prefectures as unit of region, most studies are in principle cross-section studies and relative a few studies use time-series. In growth theory, geographical variation across regions has achieved attentions and econometrics method to utilize panel data consisting of both time-series and cross-section data (Barro and Sala-i-Martin,1995)⁴. They focus on geographical convergence of GDP in the long-run. In response, there are studies on Japanese variation of GDP across regions by using panel data (e.g. Shioji, 2000)⁵. This study analyzes the geographical variation by panel data based on empirical method found in convergence in growth theory.

2. Research Method

Medical cost C_{htsjk} is defined for the h-th prefecture, t-th fiscal year, s-th type health plan, i-th medical service, j-th individual, treated at m-th hospital/clinics. Instead of using medical claim data, we use aggregated data for h, t, s (“General” and “Aged” of the Municipal Health Insurance), i-th services (“Hospitalization”, “Outpatient”, and “Dental” services).

$$C_{htsi} = \sum_{j \in J} \sum_{m \in K} C_{htsjm} \quad (1)$$

We use “City-Town-Village Municipal National Health Insurance Plan: (*Shi-Cho-Son Kokumin Kenkohoken*)” as data source which covers people residing in its region and are not covered by other public health plans or public assistance. Japanese national health insurance plan consists of two types of the health insurance plan, one is the profession based insurance, and the other is residence based insurance. The latter is the municipal insurance administered by city, town, or village. The Municipal Health Insurance provides medical insurance with the “general insured” who reside in that city, town, or village, except those who are insured by other public health insurance plans or those who are provided with health service by public assistance. Prior to 2008, the Municipal Health Insurance provides health insurance with the retired younger than 65 years old and his/her dependents. This study includes the “retired” in the “general”. The municipal also provides the aged people older than 70 years old with health insurance service through the “Health Insurance Plan for the Aged⁶”.

Thus the insured people are defined as:

N_{hts} : the average number of the insured in s-type health plan in h-th prefecture of t-th fiscal year.

¹ “The Geography and Medicare” Federal Reserve Board Working paper, 1999.

² “Geography and the Debate Over Medicare Reform,” Health Affairs, Web Exclusive reappeared in *Health Affairs* “Variations Revisited” in 2004. Survey is found in Health Affairs, 2004.

³IHEP, “*Kuni Oyobi Todoufukun Reberu de no Iryohi-no Ketteiyoutin Bunseki*”, Report. It lists 79 empirical studies, most of which use either prefecture or city-town-village as sample units of region.

⁴Barro and Sala-i-Martin, *Economic Growth*, McGraw Hill, 1995.

⁵Etsuro Shioji, “Ch.8, Nihon no Chi-iki Syotoku no Syusoku to Syakai Shihon”, in Hiroshi Yoshikawa and Masayuki Otaki ed. *Jyunkan to Seicyo no Macro Keizaigaku*, 2000. University of Tokyo Press.

⁶“*Rojin Kenko Hoken Seido*”.

$$N_{hts} = \sum_s N_{hts} = N_{htg} + N_{hta} \quad (2)$$

where “g” stands for “general” and “a” for “aged”.

E_{htsi} : the number of events when the insured receives medical services.

Because hospital/clinics present the national health insurance plan with the medical data in every month, the number of events is counted for every month. When the same medical service is provided in two consecutive months, they are counted as two separate events.

D_{htsi} : aggregate days of h-th prefecture in t-th year of the s-th health insurance.

The following measures are constructed using the above data.

$$\text{Days per event (in a month)} \quad d_{htsi}^E = D_{htsi} / E_{htsi} \quad (3)$$

$$\text{Events per population} \quad e_{htsi}^N = E_{htsi} / N_{hts} \quad (4)$$

$$\text{Days per person} \quad d_{htsi}^N = D_{htsi} / N_{hts} \quad (5)$$

$$\text{Cost per capita in real terms (1000 Yen)} \quad c_{htsi}^N = C_{htsi} / N_{hts} \quad (6)$$

Cost per capita is decomposed into (7) and (8).

$$c_{htsi}^N = \frac{C_{htsi}}{N_{hts}} = \frac{C_{htsi}}{D_{htsi}} \cdot \frac{D_{htsi}}{E_{htsi}} \cdot \frac{E_{htsi}}{N_{hts}} = c_{htsi}^D d_{htsi}^E e_{htsi}^N \quad (7)$$

$$c_{htsi}^N = \frac{C_{htsi}}{N_{hts}} = \frac{C_{htsi}}{D_{htsi}} \cdot \frac{D_{htsi}}{N_{hts}} = c_{htsi}^D d_{htsi}^N \quad (8)$$

$$\text{Cost per event} \quad c_{htsi}^E = C_{htsi} / E_{htsi} \quad (9)$$

$$\text{Cost per day} \quad c_{htsi}^D = C_{htsi} / D_{htsi} \quad (10)$$

$$C_{hts} = \sum_s \sum_i C_{htsi} = \sum_s \sum_i (C_{htsi} / N_{hts}) N_{hts} = \sum_s \sum_i c_{htsi}^N N_{hts} \quad (11)$$

By taking the difference between the period and previous period, the following equation represents the change in medical cost.

$$\Delta C_{hts} = \sum_s \sum_i \Delta C_{htsi} = \sum_s \sum_i \Delta((C_{htsi} / N_{hts}) N_{hts}) = \sum_s \sum_i (\Delta c_{htsi}^N \cdot N_{hts} + c_{htsi}^N \Delta N_{hts}) \quad (12)$$

Equation (6) $c_{htsi}^N = c_{htsi}^D d_{htsi}^E e_{htsi}^N$ is expressed in equation (13).

$$\Delta c_{htsi}^N = \Delta c_{htsi}^D \cdot d_{htsi}^E \cdot e_{htsi}^N + c_{htsi}^D \cdot \Delta d_{htsi}^E \cdot e_{htsi}^N + c_{htsi}^D \cdot d_{htsi}^E \cdot \Delta e_{htsi}^N \quad (13)$$

$$\frac{\Delta C_{ht}}{C_{ht}} = \sum_s \sum_i \left\{ \left(\frac{\Delta c_{htsi}^D}{c_{htsi}^D} + \frac{\Delta d_{htsi}^E}{d_{htsi}^E} + \frac{\Delta e_{htsi}^N}{e_{htsi}^N} + \frac{\Delta N_{hts}}{N_{hts}} \right) \cdot \frac{C_{htsi}}{C_{hts}} \right\} \quad (14)$$

The change in medical cost is expressed in terms of the growth rate of each variable.

$$\text{Growth rate of cost} \quad g(C_{ht}) = \frac{\Delta C_{ht}}{C_{ht}},$$

$$\text{Growth rate of cost per day} \quad g(c_{htsi}^D) = \frac{\Delta c_{htsi}^D}{c_{htsi}^D},$$

$$\text{Growth rate of days per event} \quad g(d_{htsi}^E) = \frac{\Delta d_{htsi}^E}{d_{htsi}^E},$$

$$\text{Growth rate of events per population} \quad g(e_{htsi}^N) = \frac{\Delta e_{htsi}^N}{e_{htsi}^N},$$

$$\text{Growth rate of the insured in s-type group} \quad g(N_{hts}) = \frac{\Delta N_{hts}}{N_{hts}},$$

$$\text{Weight of i-th medical service in total medical cost.} \quad w_{htsi} = \frac{C_{htsi}}{C_{hts}},$$

Growth of medical cost is expressed in a following equation.

$$\begin{aligned} g(C_{ht}) &= \sum_s \sum_i \{g(c_{htsi}^D) + g(d_{htsi}^E) + g(e_{htsi}^N) + g(N_{hts})\} \cdot w_{htsi} \\ &= \sum_s \sum_i \{g(c_{htsi}^D)w_{htsi} + g(d_{htsi}^E)w_{htsi} + g(e_{htsi}^N)w_{htsi} + g(N_{hts})w_{htsi}\} \end{aligned} \quad (15)$$

The growth of medical cost is the weighted sum of the cost per day, days per event, events per capita, the growth rate of the s-type insured. In the same fashion, we have the following equation.

$$\frac{\Delta C_{ht}}{C_{ht}} = \sum_s \sum_i \left\{ \left(\frac{\Delta c_{htsi}^D}{c_{htsi}^D} + \frac{\Delta d_{htsi}^E}{d_{htsi}^E} + \frac{\Delta N_{hts}}{N_{hts}} \right) \cdot \frac{C_{htsi}}{C_{hts}} \right\} \quad (16)$$

$$g(C_{ht}) = \sum_s \sum_i \{g(c_{htsi}^D) + g(d_{htsi}^E) + g(N_{hts})\} \cdot w_{htsi} \quad (17)$$

$$g(C_{ht}) = \sum_s \sum_i \{g(c_{htsi}^D)w_{htsi} + g(d_{htsi}^E)w_{htsi} + g(N_{hts})w_{htsi}\} \quad (18)$$

$$g(C_{ht}) = \sum_s \sum_i \{g(c_{htsi}^D)w_{htsi} + g(d_{htsi}^E)w_{htsi} + g(N_{hts})w_{htsi}\} \quad (19)$$

The above equation is interpreted as contribution of each factor to growth.

$$\sum_s \sum_i \{g(c_{htsi}^D)w_{htsi}\} \quad \text{Contribution of cost per capita} \quad (20)$$

$$\sum_s \sum_i \{g(d_{htsi}^E)w_{htsi}\} \quad \text{Contribution of days per population} \quad (21)$$

$$\sum_s \sum_i \{g(N_{hts})w_{htsi}\} \quad \text{Contribution of the increase in insured population} \quad (22)$$

Contribution other than population

$$\begin{aligned} &= \sum_s \sum_i \{g(c_{htsi}^D) + g(d_{htsi}^E)w_{htsi}\} = \sum_s \sum_i \{g(c_{htsi}^D)w_{htsi}\} \\ &= \sum_s \sum_i \{GrowthRate_i-th_Service_Cost_per_capita\} \cdot \{weight_i-th_Service\} \end{aligned} \quad (23)$$

a. Graphical Presentation

This study utilizes data of h=47 prefectures and t=25 years (1981-2005), s=2 types of the insured (General and Aged) in health insurance plans, i=3 services ‘‘Hospitalization’’, ‘‘Outpatient’’, and ‘‘Dental Services’’. There are four measures C/N,

C/D, D/E, E/N and D/N. In order to find patterns of medical cost, this study uses graphical presentation. In sum, y_{htsi} (C/N, C/D, D/E, E/N, D/N of the h-th region, s-th insurance: general and aged, i-th services: hospitalization, outpatient, and dental services) are plotted against years. Also the difference of the original data and the nation mean is introduced.

$$Dif(y_{htsi}) = y_{htsi} - y_{tsi}^* \quad (24)$$

where y_{tsi}^* is the national mean at t-th period, s-th insurance, and i-th service.

b. Decomposition of the Variance

The variance of the medical cost (C/N) is decomposed into ‘‘Cost per Day (C/D)’’, ‘‘Days per Event (D/E)’’, and ‘‘Events per Population (E/N)’’ as equation (24).

$$c_{htsi}^N = \frac{C_{htsi}}{N_{htsi}} = \frac{C_{htsi}}{D_{htsi}} \cdot \frac{D_{htsi}}{E_{htsi}^N} \cdot \frac{E_{htsi}}{N_{htsi}} = c_{htsi}^D \cdot d_{htsi}^E \cdot e_{htsi}^N \quad (25)$$

This is transformed into (25).

$$z = xy, x > 0, y > 0 \quad \log z = \log x + \log y$$

$$Cov(\log z, \log x) = E(\log z \cdot \log x) - \overline{\log z} \cdot \overline{\log x}$$

$$Var(\log z) = Cov(\log z, \log x) + Cov(\log z, \log y)$$

$$Var(\ln c_{htsi}^N) = Cov(\ln c_{htsi}^N, \ln c_{htsi}^D) + Cov(\ln c_{htsi}^N, \ln d_{htsi}^E) + Cov(\ln c_{htsi}^N, \ln e_{htsi}^N) \quad (26)$$

Equation (26) is transformed into (26)’ using a relationship

$$Cov(\ln c_{htsi}^N, \ln d_{htsi}^E) = Cov(\ln c_{htsi}^N, \ln c_{htsi}^D) + Cov(\ln c_{htsi}^N, \ln e_{htsi}^N)$$

$$Var(\ln c_{htsi}^N) = Cov(\ln c_{htsi}^N, \ln c_{htsi}^D) + Cov(\ln c_{htsi}^N, \ln d_{htsi}^E) \quad (26)'$$

This equation indicates that the regional variance of the medical cost (C/N) is decomposed into the sum of three terms, each of which respectively represents the covariance of the ‘‘Medical Cost per Capita(C/N)’’ with ‘‘Cost per Day (C/D)’’, ‘‘Days per Event (D/E)’’, and ‘‘Events per Population (E/N).’’ By calculating these variance and covariance, we analyze the sources of the regional variance of (C/N) and its convergence. Dividing both sides of equation (25) with the variance yields equation (27).

$$\begin{aligned} 1 &= \frac{Cov(\ln c_{htsi}^N, \ln c_{htsi}^D)}{Var(\ln c_{htsi}^N)} + \frac{Cov(\ln c_{htsi}^N, \ln d_{htsi}^E)}{Var(\ln c_{htsi}^N)} + \frac{Cov(\ln c_{htsi}^N, \ln e_{htsi}^N)}{Var(\ln c_{htsi}^N)} \\ &= b_1 (\ln c_{htsi}^N, \ln c_{htsi}^D) + b_2 (\ln c_{htsi}^N, \ln d_{htsi}^E) + b_3 (\ln c_{htsi}^N, \ln e_{htsi}^N) \end{aligned} \quad (27)$$

$$b_1 (\ln c^N, c^D) = \frac{Cov(\ln c_{htsi}^N, \ln c_{htsi}^D)}{Var(\ln c_{htsi}^N)}$$

$$b_2 (\ln c^N, d^E) = \frac{Cov(\ln c_{htsi}^N, \ln d_{htsi}^E)}{Var(\ln c_{htsi}^N)}$$

$$b_3(\ln c^N, e^N) = \frac{Cov(\ln c_{htsi}^N, \ln e_{htsi}^N)}{Var(\ln c_{htsi}^N)}$$

We can calculate b_1 , b_2 , and b_3 for the t-th period, s-th insurance, and i-th service. (26) shows how the variance is explained.

c. Econometric Analysis

In growth theory, geographical variation of GDP has been extensively analyzed based on “convergence theory” developed by Barro and Sala-i-Martin, 1995.⁷ Empirical studies have been conducted with using Japanese cross section and time-series data. For example, Shioji studies convergence of the GDP Japanese prefectures by using panel data (Shioji, 2000)⁸. This method can be applied to medical cost and associated variables.

$$y_{htsi} = \ln q_{htsi} - \overline{(\ln q_{tsi})} \quad (28)$$

q_{htsi} : variables related to medical cost including “Cost per capita (C/N)”, “Cost per Day(C/D)”, “Days per Event (D/E)”, “Events per Population (E/N)” or “Days per Population(D/N)” of h-th region, s-type insured, i-th service, and t-th period.

$\overline{\ln q_{tsi}}$: national mean for q_{htsi} . Instead of using the arithmetic mean of each variable for 47 prefectures, we use the national mean because two are different significantly due to the differences in size of regions.

$$\dot{y}_{htsi} = -\delta(y_{htsi} - y_{hsi}^*) \quad (29)$$

y_{htsi}^* is the level to which y_{htsi} is converged in the long-run. Equation (29) assumes that convergence depends on its speed defined as δ per cent annually and the differences between current level of y_{htsi} and the convergence level y_{hsi}^* . δ is positive when there is convergence.. In order to estimate δ by using annual discrete data, we transform (29) into (30).

$$y_{htsi} - y_{hsi}^* = e^{-\delta^{st}} \cdot (y_{ht-1,si} - y_{hsi}^*) + u_{htsi} \quad (30)$$

u_{htsi} is independently and identically distributed random error with $E(u_{ht}) = 0$ $E(u_{htsi}^2) = \sigma^2 I_{htsi}$, where I_{htsi} is a diagonal HT \times HT matrix which diagonal entry is unity and 0 otherwise.

$$y_{htsi} = e^{-\delta^{st}} \cdot y_{ht-1,si} + (1 - e^{-\delta})y_{hsi}^* + u_{htsi} \quad (31)$$

when the variable will converge to the same level for all regions $y_{hsi}^* = 0$, which convergence is called the “absolute convergence” (Barro and Sala-i-Martin (1995).

$$y_{itsi} = e^{-\delta^{st}} \cdot y_{ht-1,si} + u_{htsi} \quad (32)$$

We can estimate $e^{-\delta^{st}}$ in equation (32) by applying the OLS to data, then construct the “implied speed of convergence” δ^{si} . Adding additional explanatory variables yield equation (33).

⁷Barro and Sala-i-Martin, *Economic Growth*, McGraw Hill, 1995.

⁸Etsuro Shioji, “Ch.8, Nihon no Chi-iki Syotoku no Syusoku to Syakai Shihon”, in Hiroshi Yoshikawa and Masayuki Otaki ed. *Jyunkan to Seicyo no Macro Keizaigaku*, 2000. University of Tokyo Press.

$$y_{htsi} = e^{-\delta^{si}} \cdot y_{ht-1,si} + \sum_{k=1}^K \beta_{si}^k X_{htsi}^k + \sum_{j=1}^H \gamma_j D_j + \sum_{l=1}^M \tau_l T_l + u_{htsi} \quad (33)$$

where additional explanatory variables are X_{htsi}^k k-th explanatory variables whose coefficients are β_{si}^k , D_j is regional dummy variables which equals 1 when $h = j$ and 0 otherwise. Their coefficients are γ_j . T_l is year dummy variables which equals 1 when $t = l$ and 0 otherwise. Their coefficients are τ_l . As a dependent variable y_{hit} , this research uses “Cost per Day(C/D)”, “Days per Event (D/E)”, “Events per Population (E/N)” and “Days per Population (D/N)” of the s-type insured and i-th services ($\ln c_{htsi}^D, \ln d_{htsi}^E, \ln e_{htsi}^N, \ln d_{htsi}^N$). There are three categories of explanatory variables. First category is economic variables such as GDP per capita of each region. Second category is $\ln c_{htsi}^D, \ln d_{htsi}^E, \ln e_{htsi}^N, \ln d_{htsi}^N$ excluding those used as a dependent variable. The third category is the medical resources variables such as the number of beds per population, physicians per population, nurses per population, aged home capacity per population, and the use rate of hospital beds. For example, we estimate the following equation of C/D along with the $\ln d_{htsi}^E$ and $\ln e_{htsi}^N$ included in explanatory variables.

$$\ln c_{htsi}^D = e^{-\delta^{Asi}} \cdot \ln c_{ht-1,si}^D + \beta_2^{Asi} \ln d_{htsi}^E + \beta_3^{Asi} \ln e_{htsi}^N + \sum_{k=4}^K \beta_k^{Asi} X_{htsi}^k + \sum_{j=1}^H \gamma_j^{Asi} D_j + \sum_{l=1}^M \tau_l^{Asi} T_l + u_{htsi}^A \quad (33-1)$$

$$\ln d_{htsi}^E = e^{-\delta^{Bsi}} \cdot \ln d_{ht-1,si}^E + \beta_1^{Bsi} \ln c_{htsi}^D + \beta_3^{Bsi} \ln e_{htsi}^N + \sum_{k=4}^K \beta_k^{Bsi} X_{htsi}^k + \sum_{j=1}^H \gamma_j^{Bsi} D_j + \sum_{l=1}^M \tau_l^{Bsi} T_l + u_{htsi}^B \quad (33-2)$$

$$\ln e_{htsi}^N = e^{-\delta^{Fsi}} \cdot \ln e_{ht-1,si}^N + \beta_1^{Fsi} \ln c_{htsi}^D + \beta_2^{Fsi} \ln d_{htsi}^E + \sum_{k=4}^K \beta_k^{Fsi} X_{htsi}^k + \sum_{j=1}^H \gamma_j^{Fsi} D_j + \sum_{l=1}^M \tau_l^{Fsi} T_l + u_{htsi}^F \quad (33-3)$$

$$\ln d_{htsi}^N = e^{-\delta^{Gsi}} \cdot \ln d_{ht-1,si}^N + \beta_1^{Gsi} \ln c_{htsi}^D + \sum_{k=4}^K \beta_k^{Gsi} X_{htsi}^k + \sum_{j=1}^H \gamma_j^{Gsi} D_j + \sum_{l=1}^M \tau_l^{Gsi} T_l + u_{htsi}^G \quad (33-4)$$

Superscripts of A, B, F, and G are added to distinguish different estimates. Because variables of $\ln c_{htsi}^D, \ln d_{htsi}^E, \ln e_{htsi}^N$, and $\ln d_{htsi}^N$ are endogenously determined, OLS results in biased estimates. We use the instrumental variable estimation using one-period lagged variables and other variables as instruments. For example of (33-1), $\ln d_{htsi}^E$ and $\ln e_{htsi}^N$ are endogenous variables, we use one-period lagged variables $\ln d_{ht-1,si}^E, \ln e_{ht-1,si}^N$ as instruments. The similar selection of the instrumental variables is made for (33-2), (33-3) and (33-4).

3. Data

Medical cost is taken from the Ministry of Health and Welfare and Labor.⁹ The number of hospitals, clinics, and pharmacies, beds, physicians, dentists, pharmacists are taken from the Ministry of Health and Welfare and Labor¹⁰. Income

⁹Ministry of Health and Welfare and Labor, various years, *Kokumin Kenko Hoken Jigyō Nenpō* (厚生労働省『国民健康保険事業年報』).

¹⁰Ministry of Health and Welfare and Labor, every year, *Ishi, Shika-ishi Chosa, Yakuzaiishi Chosa* (厚生省・厚生労働省『医師、歯科医師調査、薬剤師調査』)

and GDP deflator of prefecture is obtained from SNA (System of National Account) at prefecture level¹¹. Consumer price index is taken from Ministry of Internal Affairs and Communications, Statistics Bureau and the Director“Regional Price Difference Index”¹². All Yen terms is adjusted by the price index at the year of 2002.

4. Preliminary Analysis

a. Growth of National Medical Cost

We divide sample into 1981-1985, 1986-1990, 1991-1995, and 1996-2000. The growth rate is calculated as the compound annual growth rate between the initial year and the last year of the five-year period¹³. Table 1 summarizes the growth of the medical cost and contribution by components. The growth rate of the number of the “Aged” is higher in 1981-1985 and 1996-2000 than other periods¹⁴. The former is due to the introduction of the “Health Insurance Plan for the Aged” and the latter corresponds to the growth of the number of the aged population since the late 1990s. Then new health insurance expanded the insured by covering all population older than 70 years old. Table 1 also indicates the growth of the medical cost by types of services using the national means. First panel indicates the share of each service in the medical cost of the Municipal Health Insurance Plan. Shares of the “Aged Hospitalization” and “Aged Outpatient” had grown to 27 per cent and 23 percent respectively¹⁵. Total medical cost had growth rate 6.7% (1981-1985), 3.8% (1986-1990), 4.8 % (1991-1995), 4.3% (1996-2000). Of the 4.3% growth rate in 1996-2000 period, the “Aged Hospitalization” cost constitutes 1.6% and the “Aged Outpatient” 1.3%. Almost 80 % of the growth rate of medical cost came from the services for the aged services. Contribution of the growth of the number of population for the “Aged Hospitalization” is 1.7%, “Aged Outpatient” is 1.5% in 1996-2000. Most of medical cost growth (4.26% in 1996-2000 was accounted by the increase in the numbers of the insured (2.8%), while only small part was accounted by other factors (C/D, D/E, E/N). (1.46%).

-----Table 1. Growth of Population in the Municipal Health Insurance Plan -----

b. Geographical Trend

i. GDP and Medical Resources

Using graphical presentations, this section analyzes trend and the variance of measures. Figures 1-1 to 1-9 (Appendix) summarizes GDP and medical resources. Figure 1-1 of GDP indicates that real GDP had not grown much since the 1990s. There were wide differences across regions. Tokyo had maintained the highest GDP that was twice high as the lowest GDP of Okinawa. The variance had, however, shrunk until 2000s, then the variance had expanded again. Figure 1-2 shows doctors per population, 1-2 nurses per population, both of which grew steadily over time, but had large regional differences. For example, Tokyo had the highest doctors per population ratio, while it had lower nurses per population. Beds per population had different pattern in that it had increased up to 1980s, then it had started to decline in the 1990s. This may reflect the government policy to reduce the number of beds. There were wide regional variances. For example, Kochi had by far the highest rate, while Saitama had the lowest. Saitama has also the lowest doctors per population and nurses per population rate. Under investment in Saitama deserves further investigation.

ii. Hospitalization Services

¹¹Economic and Social Research Institute, Cabinet Office, SNA Data (経済企画庁・内閣府経済社会研究所『県民所得統計年報』)

¹²Ministry of Internal Affairs and Communications, Statistics Bureau and the Director, every year, *Zen Koku Bukka Tokei Cyosa Hokoku*, 総理府統計局・総務省統計局『全国物価統計調査報告』)

¹³Growth rate is calculated as $\sqrt[t]{(X_t / X_{t-5})} - 1$ where $t=1986, 1991, 1996,$ and 2001.

¹⁴The growth reflects the introduction of the “Health and Medical Service Law for the Aged (*Rojin Kenko Hoken Seido*)” in 1983 by replacing the prior insurance plan for the aged.

¹⁵Medical cost of the Municipal Health Insurance Plan constitutes about one-thirds of total medical cost of medical cost of Japan. For the aged it constitutes about 70 percent of Japan. Ministry of Health, Welfare, and Labor, various years, *Kokumin Iryohi* (厚生労働省『国民医療費』).

Figures 2-1 to 2-10 summarize cost measurements for the “General” and “Aged” of “Hospitalization”. Figures display the trend and the variances with the nation mean along with individual data including prefectures of Hokkaido, Saitama, Tokyo, Nagano, Osaka Tokushima, Kochi, Fukuoka and Okinawa, all of which show unique profiles. The medical cost of per capita (C/N) for the “General” had increased up to the early 1980s, while it had been flattened in the 1990s. In contrast, the cost per day (C/D) had not increased up to 1990s, since then it had started to grow. “Days per Event (D/E)” and “Events per Person (E/N)” had increased moderately up to the early 1990s, then they had declined. The medical cost containment by the government had affected (D/E) and (E/N). There had been wide geographical variations across regions.

The medical cost of the “Aged Hospitalization” had been stable in the 1990s, which might reflect the cost containment of the regions with the higher medical cost. Cost per day (C/D) had started to increase in 1992 in the same manner with the “General Hospitalization”. The “Days per Event (D/E)” and “Events per Population (E/N)” had declined significantly in the 1990s for the aged. As a result, the “Days per Population(D/N)” had peaked in the late 1980s and since then continued to decline. In particular, regions with higher events per population had reduced their rates in the 1990s (Figure 2-10). Regions with higher “Cost per Day(C/D)” tended to have lower days per event (D/E) and events per population. In sum, the large variances of the aged in the 1980s had rapidly converged by the early 2000s. We should analyze the different patterns of convergence between the general and aged.

iii. Outpatient Services

Unlike “Hospitalization”, cost per capita (C/N) for “Outpatient” had increased both for the “General” and “Aged” up to 1997 (Figure 2-11, 2-16), then it became stable until 2003. The aged had become more stable than the general. The increase in C/N for the “Aged Outpatient” is contrasted with the stable C/N for the “Aged Hospitalization.” Although the events per population (E/N) for the “General” and “Aged” had increased, “Days per Population (D/N)” had remained fairly stable over periods due to the decline in “Days per Event (D/E)”. There are some outliers. For example, Hiroshima had recorded the highest rates C/N and Tokushima had rapidly increased the rates while Okinawa and Tokyo had maintained the lowest rates. “Cost per Day (C/D)” had increased steadily. Okinawa had the highest rates of (C/D) while Tokyo had achieved lower rates both for the “General” and “Aged”. Although Okinawa and Tokyo had long achieved lower C/N for outpatient, Okinawa had the highest while Tokyo had lower (C/D). The reasons behind this deserve further examinations. Days per population (D/N) had increased for the “General” in the mid-1990s, while that for the “Aged” had been stable over the periods. Compared with the “General Outpatient”, the “Aged Outpatient” had wider variations in D/N across regions.

iv. Dental Services

Figure 2-21 to 2-30 summarizes “Dental” services. There were upward trends for C/N and C/D. Unlike other services, the increase in D/N is due to the rise in E/N. There are large differences across regions for the “Aged” compared with “General”. Although both Fukuoka and Osaka had higher cost per capita (C/N), Fukuoka had longer “Days per Event (D/E)” while Osaka had higher “Event per Population (E/N)” than most regions. Okinawa had the lowest C/N both for the “General” and “Aged” because “Events per Population (E/N)” had been far lower than other regions. Patterns of dental services are totally different from the hospitalization and outpatient. These outliers require further investigation with focusing on region specific effects.

v. Comparison

Due to many data, graphical presentation is too difficult to draw stylized patterns. Figure 3-1 to 3-5 (Appendix) show the means of C/N, C/D, D/E, E/N, and D/N by each medical service. Cost per day (C/D) for the hospitalization had been stable up to 1992, since then it had started to increase, while C/D for the outpatient dental services had continued to rise except for the early 2000s. Days per population (D/N) for the general had been stable until the late 1990s, while those for the aged had declined since the late 1980s. Introduction of the long-term case insurance in 2000 is associated with the decline of (D/N). Events per population (E/N) had peaks in 1995 for the general and 1989 for the aged. Both of which had started to increase in the early 2000s, which reasons are not clear without further investigation.

5. Geographical Variance

a. Overview

As seen above, there are significant regional variations of medical resources and cost across prefectures. In order to identify the stylized variation across regions, this study first uses graphical presentation. We use the differences of original measures from the national means.

$$Dif(y_{htsi}) = y_{htsi} - y_{tsi}^* \quad (24)$$

Figure 4-1 to 4-30 in Appendix exhibit the regional variations. There was the convergence of the aged services for most measures, while there was no such convergence for general services. Also some regions were shown to have unique movement. For example, as to the “Aged Hospitalization”, Okinawa and Nagano were outliers, while as to the “General Outpatient”, Okinawa and Hiroshima were outliers.

Regional variation can be summarized by the statistical measures of the coefficient of variation (CV). Figure 5-1 to 5-4 summarizes the CV of the related measures in natural log form. For example, CV of cost per capita (C/N) had downward trend for the “Aged Hospitalization”, “Aged Outpatient”, and “General Dental” while those of the “General Hospitalization” and “General Outpatient” had been stable. In particular, CV for the “Aged Hospitalization” had a steep downward slope around year 2000 when the Long term Care Insurance was introduced. CV for Ln (C/D) had similar trends. CVs for Ln (D/N) exhibit that all medical services except for the “General Dental” had shown the downward slopes. CV for the “General Hospitalization” had a downward slope up to 1992, since then it had increased. Dental services had followed special trend which are distinguished from the other services. The variance of $\ln c_{htsi}^N$ for the “Aged Hospitalization” and “Aged Dental” had declined significantly over periods, which trend indicates that the differences across prefectures had become smaller while the variance of “General Hospitalization” and “General Outpatient” had been stable in the long run. In the same manner, the variance of C/D, D/E, and E/N moves significantly.

b. Decomposition of the Variance

We are concerned is the magnitude and sources of the variance. To answer this question equation (25) and (26) are applied.

$$Var(\ln c_{htsi}^N) = Cov(\ln c_{htsi}^N, \ln c_{htsi}^D) + Cov(\ln c_{htsi}^N, \ln d_{htsi}^E) + Cov(\ln c_{htsi}^N, \ln e_{htsi}^N) \quad (26)$$

Figures 6-1 to 6-6 (Appendix) summarize the results. The variance of the “Aged Hospitalization” had declined significantly over the periods up to 2000, while that of the “General Hospitalization” had been flat for the periods. Again the decline in 2000 might reflect the introduction of the Long-term Care Insurance. The covariance of $Cov(\ln c_{tsi}^N, \ln c_{tsi}^D)$ had been negative through out the periods which indicates that the medical cost per day ($\ln c_{tsi}^D$) is negatively correlated with the ($\ln c_{tsi}^N$) for the hospitalization services. This is interpreted that the regions with higher C/D have lower C/N. $Cov(\ln c_{tsi}^N, \ln d_{tsi}^E)$ had been stable at 0.1-0.2 range except for the sudden drop in 2000. A striking feature is that $Cov(\ln c_{tsi}^N, \ln e_{tsi}^N)$ had been similar to the variance of $Var(\ln c_{tsi}^N)$. The variance of $\ln c_{tsi}^N$ is mostly explained by $Cov(\ln c_{tsi}^N, \ln e_{tsi}^N)$. In contrast, the variance of $\ln c_{tsi}^N$ of “General Hospitalization” had not shown convergence. $Cov(\ln c_{tsi}^N, \ln c_{tsi}^D)$ again indicates the negative sign, while $Cov(\ln c_{tsi}^N, \ln d_{tsi}^E)$ had been stable too. $Cov(\ln c_{tsi}^N, \ln e_{tsi}^N)$ is similar with the $Var(\ln c_{tsi}^N)$. These results are also interpreted by (26) which
