

1
2
3 141 associations were obtained for type1 to type3 in any combinations. When we performed the
4
5
6 142 same analysis between type4 and the pooled genotypes of type1 to type3, we again obtained a
7
8
9
10 143 significant difference ($p=4.8 \times 10^{-6}$, OR=1.96, 95%CI: 1.47-2.62).

11
12
13 144 We further examined the specific association of rs738409 with type4 subgroup by
14
15
16 145 using the case/control association results of the initial genome scan. 529 NAFLD patients
17
18
19 146 were divided into 202 patients with type1 to type3 and 327 patients with type4, and genotype
20
21
22 147 distributions of rs738409 in each subgroup were compared with those of 932 control subjects.
23
24
25 148 Exact trend test returned an extremely strong association of rs738409 with type4 subgroup
26
27
28
29 149 ($p=1.7 \times 10^{-16}$, OR=2.18, 95%CI: 1.81-2.63) whereas no association was obtained for type1 to
30
31
32 150 type3 subgroups ($p=0.41$).

33
34
35 151

36 37 38 152 **Association of rs738409 genotypes with clinical traits**

39
40
41 153 The quantitative effects of rs738409 genotypes to clinical traits were examined by
42
43
44
45 154 multivariable regression adjusted for age, sex and BMI (statistical calculation 1, Table 3).
46
47
48 155 Five categorical ordinals, namely, anti-nuclear antibody (ANA), Brunt grade, Brunt stage, fat
49
50
51 156 deposition and iron deposition, were also tested by an ordinal logistic regression analysis.
52
53
54 157 Potential associations ($p<0.05$) were obtained for 11 traits, namely, aspartate transaminase
55
56
57 158 (AST), alanine aminotransferase (ALT), type IV collagen 7S, hyaluronic acid, hemoglobin

1
2
3 159 A1c (HbA1c), fasting immunoreactive insulin (IRI), fasting plasma glucose (FPG), platelet
4
5
6 160 count (PLT), Brunt grade, fat deposition and iron deposition (Table 3). When the results
7
8
9 161 were further adjusted for Matteoni type (statistical calculation 2), AST, hyaluronic acid,
10
11
12 162 HbA1c, FPG, PLT, Brunt grade and iron deposition showed p -values smaller than 0.05. The
13
14
15 163 level of serum triglyceride was not significant in the initial analysis, but became significant
16
17
18 164 after being adjusted for Matteoni's type ($p=0.013$). Among them, only three traits, namely,
19
20
21 165 hyaluronic acid, HbA1c and iron deposition, remained significant ($p<0.0021$) after
22
23
24 166 Bonferroni's correction for multiple testing (Table 3).
25
26
27
28
29 167

30 31 32 168 **Associations of previously reported SNPs with NAFLD**

33
34
35 169 Previous genetic studies identified four chromosomal loci, namely, *LYPLAL1* at 1q41,
36
37
38 170 *GCKR* at 2p23, *NCAN* at 19p12 and *PPP1R3B* at 8p23.1, associated with NAFLD in
39
40
41 171 populations of European descent [14]. We examined whether or not the associations were
42
43
44 172 reproduced in the Japanese population by extracting genotype information of SNP markers
45
46
47 173 corresponding to these four loci. As shown in Table 4, the association of rs780094 in *GCKR*
48
49
50 174 with NAFLD was at the border of significance ($p=0.011$, OR=0.82, 95%CI: 0.70-0.91) in the
51
52
53 175 case/control analysis. However, the association was lost when examined between rs780094
54
55
56 176 genotypes and Matteoni types. There were no associations of rs2228603 in *NCAN* and
57
58
59
60
61
62
63
64
65

1
2
3 177 rs12137855 in *LYPLALI* with either NAFLD or Matteoni types. Rs4240624 in *PPP1R3B*
4
5
6 178 was not in the SNP array used for this study, and this marker was not polymorphic or at a very
7
8
9
10 179 low frequency in the Japanese (0 in 90 chromosomes in the Japanese result of the
11
12
13 180 International HapMap Project).

1
2
3 181 **Discussion**
4
5

6 182 NASH is a type of hepatic steatosis in NAFLD with poor prognosis accompanying
7
8
9
10 183 liver fibrosis, and subsequent liver cirrhosis and hepatocellular carcinoma [18]. Despite the
11
12
13 184 extensive biochemical and histological investigation of NAFLD, whether or not NASH forms
14
15
16 185 a distinct disease entity in NAFLD still remains unclear. The principle aim of this study was
17
18
19 186 to identify the genetic factors related to the pathogenic status of NAFLD by collecting DNA
20
21
22 187 samples of Japanese NAFLD patients with critically diagnosed disease status by liver biopsy.
23
24
25 188 To our knowledge, this is the first GWA study of NAFLD using patients with known
26
27
28 189 histology-based Matteoni type. In the initial association study using pooled genotyping
29
30
31
32 190 results of all the cases, we found a significant association of the *PNPLA3* gene at chromosome
33
34
35 191 22q13.31 with NAFLD in the Japanese. Rs738409 which showed the strongest association
36
37
38 192 with NAFLD in the GWA study of Caucasians was also genotyped and its strongest
39
40
41 193 association with NAFLD was confirmed. These results were in agreement with the former
42
43
44
45 194 GWA analyses in populations of European descent and in Hispanics, giving strong evidence
46
47
48 195 of the involvement of *PNPLA3* in NAFLD beyond ethnicities. Rs738409 is located in exon3
49
50
51 196 of the *PNPLA3* gene which is expressed in the liver and adipose tissue. This SNP introduces
52
53
54 197 an amino acid substitution from isoleucine to methionine (I148M), and biological studies
55
56
57 198 demonstrated that its risk allele (G) abolishes the triglyceride hydrolysis activity of *PNPLA3*
58
59
60
61
62
63
64
65

1
2
3 199 [19]. These observations strongly suggest rs738409 to be a causative genetic variation for
4
5
6 200 NAFLD. However, future genomic analyses by fine mapping or extensive sequencing may
7
8
9
10 201 identify additional genetic determinants within the *PNPLA3* locus.

11
12
13 202 In the current study we did not find other genetic loci showing genome-wide
14
15
16 203 significance ($p < 1.0 \times 10^{-7}$). However, two additional chromosomal loci with p -values
17
18
19 204 being smaller than 1×10^{-5} were identified on chromosome 1p (rs11206226) and chromosome
20
21
22 205 4p (rs1390096) neither of which has been reported as being associated with NAFLD in
23
24
25 206 Caucasians (supplementary table 1). Statistical calculation by taking their allele frequencies
26
27
28
29 207 and effect sizes into account showed that approximately three times as many case and control
30
31
32 208 samples are required to obtain sufficient statistical power (>0.8) for genome wide significance.
33
34
35 209 Hence, further confirmation is required using a larger collection of patients and controls
36
37
38 210 although they may be potential candidates of low-penetrance genes for susceptibility to
39
40
41 211 NAFLD in Japanese.

42
43
44
45 212 Subsequent analyses through comparison of genotype distribution among four
46
47
48 213 subgroups of NAFLD (type1 to type4) categorized by Matteoni's classification revealed that
49
50
51 214 the seven NAFLD-associated SNPs in the *PNPLA3* gene were also significantly associated
52
53
54 215 with the pathogenic status of NAFLD. There were also marked differences in genotype
55
56
57 216 distribution of rs738409 between type4 subgroup and the other three groups ($p=4.8 \times 10^{-6}$,

1
2
3 217 OR=1.96, 95%CI: 1.47-2.62 between type4 and pooled genotypes of type1 to type3).
4
5
6 218 Moreover, a case/control analysis of rs738409 between Matteoni type4 and controls returned
7
8
9 219 a surprisingly strong association ($p=1.7 \times 10^{-16}$) which was much stronger than the initial
10
11
12 220 analysis using all NAFLD cases ($p=1.4 \times 10^{-10}$), whereas the analysis using Matteoni type1 to
13
14
15 221 type3 as cases didn't show significance ($p=0.41$). There were differences in the score of
16
17
18 222 HOMA-IR and hs-CRP, indicators of insulin resistance and inflammation, respectively,
19
20
21
22 223 between Matteoni type1 to type3 and type4 subgroups (Table 1). Our results provide
23
24
25 224 compelling evidence that NASH corresponding to Matteoni type4 is both a clinically and
26
27
28 225 genetically different disease subset from other spectrums of NAFLD. Previous studies
29
30
31
32 226 showed association between *PNPLA3* and fatty liver, inflammation, fibrosis grade and NASH
33
34
35 227 [13]. In our result, strong association between rs738409 and fatty liver was not observed by
36
37
38 228 comparing control and Matteoni type1. In addition, strong association between rs738409
39
40
41 229 and lobular inflammation was not observed by comparing Matteoni Type1 and Type2. In
42
43
44 230 contrast, a strong association between rs738409 and NASH was observed. Although we
45
46
47 231 could not observe the strong association between rs738409 and fibrosis stage, strong
48
49
50 232 association between rs738409 and Hyaluronic acid suggests that an association exists between
51
52
53 233 *PNPLA3* and fibrosis.

54
55
56
57 234 We have also undertaken association analyses of rs738409 and clinical traits in the
58
59
60
61
62
63
64
65

1
2
3 235 patients. The multivariable regression analysis adjusted for age, sex, BMI and Matteoni type
4
5
6 236 followed by the correction for multiple testing revealed hyaluronic acid and HbA1c as being
7
8
9
10 237 significantly associated with rs738409. Hyaluronic acid is one of the principle components
11
12
13 238 of the extracellular matrix and its involvement in fibrosis has been previously suggested [20].
14
15
16 239 This may indicate another possible functional involvement of *PNPLA3* in the progression of
17
18
19 240 liver fibrosis by influencing the circulating hyaluronic acid levels. A weak association of
20
21
22 241 rs738409 and HbA1c levels was observed in our study population. However, there are no
23
24
25 242 reports to date indicating such an association, and confirmation with different sample sets is
26
27
28
29 243 needed for definitive conclusion. Also, the association between rs738409 and iron
30
31
32 244 deposition was demonstrated by an ordinal logistic regression analysis. Since the
33
34
35 245 association still remained after the results were adjusted with Matteoni type, rs738409 may
36
37
38 246 play a functional role in the oxidative stress through iron absorption in the liver.

41 247 Recently, a genetic analysis of Japanese NAFLD patients was reported demonstrating
42
43
44
45 248 a significant association in the increase of AST, ALT, ferritin levels and fibrosis stage (Brunt
46
47
48 249 stage) and in the decrease of serum triglyceride with the risk allele (G) of rs738409 [12]. In
49
50
51 250 our study, the association of rs738409 with AST ($p=1.2 \times 10^{-4}$) and ALT ($p=0.0016$) was
52
53
54 251 reproduced and that of AST still remained after the results were adjusted for Matteoni type
55
56
57 252 ($p=0.038$). No association was observed for ferritin level. Brunt stage was available for

1
2
3 253 Matteoni type4 patients only in our study. Although the odds ratio was slightly high
4
5
6 254 (OR=1.28, 95%CI: 0.95-1.72), it was not possible to examine the association. In addition,
7
8
9 255 the inverse association of the risk allele of rs738409 with decrease of serum triglyceride was
10
11
12 256 confirmed in our study ($p=0.013$ after being adjusted for Matteoni type). For all of these
13
14
15
16 257 biomarkers, however, the significance was lost after the correction for multiple testing.
17
18

19 258 A replication analysis of other genetic loci that had been reported for their
20
21
22 259 association with NAFLD in East coast white Americans [14] was performed in our sample
23
24
25 260 collection. We confirmed the association of rs780094 in *GCKR* with NAFLD in a
26
27
28 261 case/control analysis but at a much weaker level ($p=0.011$, OR=0.82, 95%CI: 0.70-0.95) than
29
30
31 262 that shown for the populations of European-descent. No associations were found for
32
33
34
35 263 *LYPLALI* and *NCAN* loci in our study. There are several reasons to explain such differences,
36
37
38 264 such as the insufficient statistical power with a limited number of study subjects in our study
39
40
41 265 due to the difficulty in the collection of a larger number of histologically diagnosed NAFLD
42
43
44 266 patients. The difference in genetic background between the Japanese and Europeans is also
45
46
47
48 267 conceivable. Indeed, the risk allele frequency of rs12137855 in *LYPLALI* was 0.944 in our
49
50
51 268 control subjects but approximately 0.79 in the European populations [14]. Similarly, there was
52
53
54 269 a difference in the risk allele frequency of rs2228603 in *NCAN* (0.049 in Japanese and 0.08 in
55
56
57 270 Europeans). Rs4240624 in *PPP1R3B* was not polymorphic in the Japanese while its risk

273 **Materials and Methods**

274 **Ethics Statement**

275 In compliance with the Declaration of Helsinki, ethical approval for this study was
276 given by the respective Institutional Review Board and subject written informed consent were
277 obtained for all subjects (Ethical committee of Nara City Hospital; Ethical committee of
278 Saiseikai Suita Hospital; Medical Ethics Committee of Kanazawa University; Ethics
279 committee of Kyoto Prefectural University of Medicine; Ethical Committee of Aichi Cancer
280 Center; Ethical Committee of Kochi Medical School, Kochi University; Ethics Committee of
281 Tokyo Women's Medical University; Ethical Committee on Kawasaki Medical School and
282 Kawasaki Medical School Hospital; Ethical Committee of Juntendo University; Ethics
283 Committee of Yamagata University School of Medicine; Ethical Committee of the Ikeda
284 Municipal Hospital; Institutional Review Board and Ethics Committee of Kyoto University
285 School of Medicine).

286

287 **Study population**

288 A total of 543 patients histologically diagnosed for NAFLD in 2007-2009 were
289 recruited through the Japan study of Nonalcoholic Fatty Liver Disease. Biopsy specimens
290 were stained with H&E and Masson's trichrome for morphological review and assessment of

1
2
3 291 fibrosis. Perl's Prussian blue was performed to evaluate iron load. Biopsy specimens were
4
5
6 292 reviewed by a hepatopathologist (T.O). NAFLD patients were classified into four
7
8
9
10 293 categories by liver histology according to the classification by Matteoni *et al* [2] as follows;
11
12
13 294 type1: fatty liver alone, type2: fat accumulation and lobular inflammation, type3: fat
14
15
16 295 accumulation and ballooning degeneration, type4: fat accumulation, ballooning degeneration,
17
18
19 296 and either Mallory-Denk body or fibrosis. With these criteria, the 543 patients were
20
21
22 297 classified as type1; 102, type2; 75, type3; 31 and type4; 335. The histological grade and
23
24
25 298 fibrosis stage were also evaluated by the classification of Brunt *et al* [21] for advanced
26
27
28
29 299 NAFLD cases (type3 and type4) as follows; grade 1: steatosis involving up to 66% of biopsy,
30
31
32 300 occasional ballooned zone 3 hepatocytes and absence or mild portal chronic inflammation,
33
34
35 301 grade2: steatosis, ballooning hepatocytes mild to moderate chronic inflammation, grade3:
36
37
38 302 panacinar steatosis, ballooning and disarray obvious and mild or portal mild to moderate
39
40
41 303 inflammation, stage1: perivenular and/or perisinusoidal fibrosis in zone3, stage2: combined
42
43
44 304 pericellular portal fibrosis, stage3: septal/bridging fibrosis, stage4: cirrhosis. The degree of
45
46
47
48 305 fat deposition was evaluated by amount of fat droplets as observed under the microscope as
49
50
51 306 follows; 0: <5%, 1: 5-<10%, 2: 10-<34%, 3: 34-<67%, 4: >67%. The degree of iron
52
53
54 307 deposition was categorized by the presence of granules of free iron observed under the
55
56
57 308 microscope as follows; 0: absence by x400, 1: easily identifiable by x400 and rarely
58

309 identifiable by x250, 2: identifiable by x100, 3: identifiable by x25, 4: identifiable at lower
310 than x25.

311 Inclusion criteria for NAFLD patients were as follows; (i) no history of alcoholism,
312 (ii) no history for HBV/HCV/HIV infection, (iii) diagnosed by liver biopsy, (iv) information
313 regarding age and BMI available. The sex of two samples was unknown, and was imputed
314 from the results of the genome scan. As general Japanese population controls, the genome
315 scan results of 942 healthy Japanese volunteers from Aichi Cancer Center Hospital and
316 Research Institute were used [22].

317
318 Anthropometric and laboratory evaluation

319 We employed conventional methods for the measurement of anthropometry (height,
320 weight, amount of visceral fat and abdominal circumscript). BMI was calculated from the
321 measurements. The following biochemical/hematological/immunological traits were also
322 measured by conventional methods; aspartate aminotransferase (AST), alanine
323 aminotransferase (ALT), γ -glutamyl transpeptidase (GGT), albumin, total bilirubin,
324 cholinesterase, type IV collagen 7S, hyaluronic acid, triglyceride, total cholesterol,
325 hemoglobin A1c (HbA1c), fasting immunoreactive insulin (IRI), fasting plasma glucose
326 (FBS), high sensitive CRP (hs-CRP), adiponectin, leptin, ferritin, uric acid, and platelet (PLT)

1
2
3 327 count. Anti nuclear antibody (ANA) was measured by ELISA and categorized by the
4
5
6 328 detection limit in a serial dilution as follows; 0: <40x, 1: 40-80x, 2: 81-160x, 3: 160x, 4:
7
8
9
10 329 >320x. Homeostasis model assessment-insulin resistance (HOMA-IR) was calculated from
11
12
13 330 the measurements. Patients were assigned a diagnosis of diabetes mellitus (DM) when they
14
15
16 331 had documented use of oral hypoglycemic medication, a random glucose level >200 mg/dl, or
17
18
19 332 FPG >126 mg/dl. Hyperlipidemia was diagnosed with the cholesterol level being
20
21
22 333 >200mg/dl and/or triglyceride level being >160mg/dl. Hypertension was diagnosed when
23
24
25 334 the patient was taking antihypertensive medication and/or had a resting recumbent blood
26
27
28
29 335 pressure \geq 140/90 mmHg on at least two occasions.
30

31
32 336

33 337 **DNA preparation**

34
35
36
37
38 338 Genomic DNA was extracted from peripheral blood mononuclear cells by standard
39
40
41 339 phenol-chloroform extraction and resuspended in TE buffer. DNA concentration and purity
42
43
44
45 340 were measured with Nanodrop 1000 spectrophotometer (Thermo Scientific, Waltham, MA,
46
47
48 341 USA). The samples were stored at -20°C until use.
49

50
51 342

52 53 54 343 **Genome-wide genotyping and quality control**

55
56
57 344 Genome scan was conducted for 543 patients with NAFLD and 942 healthy subjects
58
59

1
2
3 345 using Illumina Human 610-Quad Bead Chip on a Bead Station 500G Genotyping System
4
5
6 346 (Illumina, Inc., San Diego, CA, USA) and subjected to the following quality controls.
7
8
9
10 347 Initially, ten patients and six control subjects were removed due to low call rates (<0.99).
11
12
13 348 Regarding the SNP markers, 85,472 SNPs with minor allele frequency of smaller than 0.01 in
14
15
16 349 either case or control group, 6,479 SNPs with lower success rates (<0.98) and 35 SNPs with
17
18
19 350 distorted Hardy-Weinberg equilibrium ($p < 10^{-7}$) were removed, resulting in 484,751 SNP
20
21
22 351 markers being used for analysis. Principal component analysis by EIGENSOFT [17]
23
24
25 352 including phase II HapMap (<http://hapmap.ncbi.nlm.nih.gov/>) samples identified no samples
26
27
28 353 that were deviated from the Japanese population. Subsequently, the degree of kinship
29
30
31
32 354 between individuals was examined by pi-hat in PLINK 1.07
33
34
35 355 (<http://pngu.mgh.harvard.edu/purcell/plink/>) [23]. Of the eight pairs of samples (four case
36
37
38 356 pairs and four control pairs) showing high degrees of kinship (PI-HAT>0.4), the sample with
39
40
41
42 357 the lower call rate in each pair was removed. After these steps, 529 case and 932 controls
43
44
45 358 were used for the analysis.

46
47
48 359
49
50
51 360 **Statistical analysis**

52
53
54 361 A case/control association analysis was performed by exact trend test between
55
56
57 362 NAFLD patients and control subjects [24]. The correction of obtained p -values for

1
2
3 363 population stratification was performed using EIGENSTRAT [17]. In addition, an
4
5
6 364 association between Matteoni classification (type1 to type4) and additive model of genotype
7
8
9
10 365 for each SNP was examined using Jonckheere-Terpstra test for NAFLD patients.
11
12
13 366 Assessment of population stratification of inflation of p -value was carried out by the genomic
14
15
16 367 control method for asymptotic trend test [25]. Association between each quantitative trait
17
18
19 368 and the genotype of significant SNPs in NAFLD patients were calculated by multivariable
20
21
22 369 linear regression or multivariable ordinal regression adjusted for age, sex and BMI. Each
23
24
25 370 quantitative trait was transformed as follows; natural log for ALT, AST, HOMA-IR, HbA1c,
26
27
28
29 371 IRI, triglyceride, total bilirubin, adiponectin, hs-CRP, hyaluronic acid, leptin, reciprocal
30
31
32 372 number for albumin, cholinesterase, type IV collagen 7S and square root for uric acid and
33
34
35 373 ferritin. The values of FPG, PLT, total cholesterol, amount of visceral fat, and abdominal
36
37
38 374 circumference were not transformed. For each trait, values that were within only 4 S.D. were
39
40
41 375 included for analysis. LD indices were calculated by default setting of Haploview [26] and
42
43
44 376 the LD block was defined manually.
