Acknowledgement

Epidemiological data were provided from Infectious Disease Surveillance Center at NIID (Drs T. Sunagawa and K. Oishi).

We acknowledge NICs in Laos, Taiwan CDC, Myanmar, and Viet Nam (HCM), and 76 Local Public Health Laboratories in Japan for sharing clinical specimens and virus isolates.

Nucleotide sequence data of viruses for phylogenetic analyses of HA and NA genes are used from GISAID.

Epidemiology of the 2013/14 season (since September, 2013)

Influenza activity in Japan from September 2013 to February 7 2014

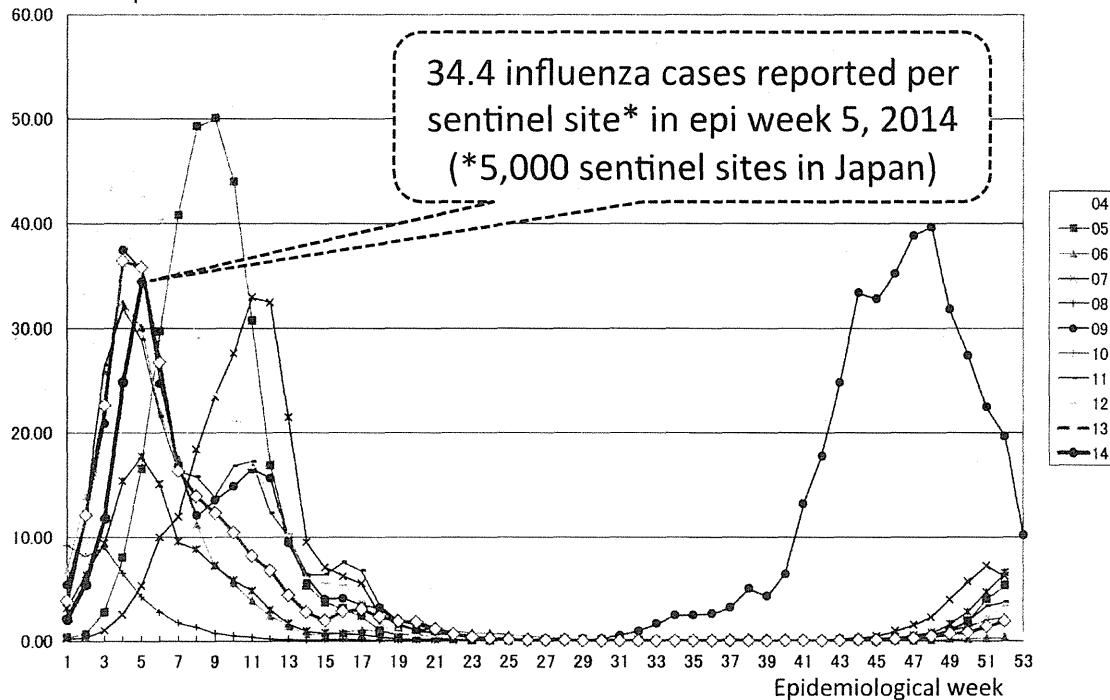

- Influenza activity based on the weekly case number per sentinel hospital in the 2013/14 season started later than previous seasons, but sharply increased after new year' holiday and has been increasing greatly at the moment.
- Estimated influenza case numbers in weeks 4 and 5 were 1,320,000 and 1,870,000, respectively, and cumulative number was 4,620,000 (as of week 5). Age distribution of influenza cases per week since week 46, 2013 exhibited that 5-9 year-old group was predominant and followed by 10-14 and 0-4 year-old groups.
- As of February 7, 2014, total 1667 viruses were isolated/detected since week 36, 2013. Of those viruses, A(H1N1)pdm09 (39%) and A(H3N2) virus (35%) were co-circulated with almost similar proportion. Notably, greatly increased numbers of A(H1N1)pdm09 virus were observed since week 2, 2014 and the virus predominated (52%) in recent 5 weeks.
- Both B/Victoria-lineage and B/Yamagata-lineage viruses were co-circulated, but B/Yamagata-lineage viruses (63%) predominated over B/Victoria-lineage viruses (37%).

Viruses provided by NICs

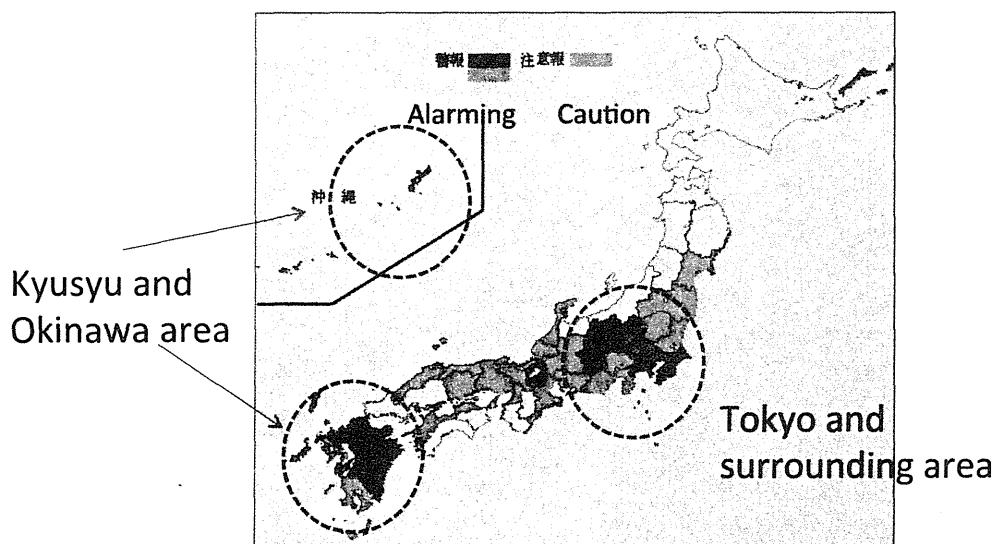

- Viruses provided by NICs are summarized in a table in page 9.
- Antigenic and genetic characterizations of the viruses provided by NICs were performed by WHO CC Tokyo and the data were included in either data package distributed for 1st teleconference (December 19, 2013), 2nd teleconference (January 23, 2014) or vaccine composition meeting held in WHO-HQ (February 17-20, 2014).

A(H1N1)pdm09 virus

Antigenic and Phylogenetic analyses:

- Total 52 A(H1N1)pdm09 viruses were subjected to antigenic analysis by hemagglutination inhibition (HI) tests. The majority of A(H1N1)pdm09 viruses analyzed was isolated between September and December 2013. The genetic group of the HA gene are listed together with HI profiles in the HI table.
- All viruses tested reacted well with antisera raised against egg propagated A/California/7/2009. There were not antigenic variant viruses with mutation(s) in 153-157 region of HA gene at the moment.
- Similarly, the vast majority of test viruses were well covered with antiserum raised against cell-propagated A/Narita/1/2009 and only 2% of test viruses showed 8-fold reduced HI titer to the homologous titer.
- Ferret antiserum raised against a high growth reassortant (HGR) A/California/7/2009 X-179A also covered well all test viruses, but one virus each from Japan and Laos showed 8-fold reduced HI titer to A/California/7/2009 X-179A antiserum.
- Forty-three (12%) oseltamivir/permivir resistant viruses with H275Y substitution in the NA protein have been detected in Japan. A community cluster occurred in Sapporo and its neighboring cities (see detail in the section of antiviral-resistance viruses). Those resistant viruses were antigenically indistinguishable from the sensitive viruses and were antigenically similar to A/California/7/2009.
- Phylogenetic analysis of the HA and the NA genes were correlated well each other. All recent test viruses fell into group 6 with amino acid substitution of D97N, K283E, E499K in the HA protein. Group 6 was further subgrouped 6B with K163Q, A256T and 6C with V234I. Viruses belonging to subgroup 6B (79%) were predominant than those belonging to subgroup 6C (21%). Those subgroups were antigenically indistinguishable from each other.
- In phylogenetic tree of NA gene, all antiviral resistant viruses detected in Japan as well as in China belonged to subgroup with N386K in group 6B, whereas the resistant viruses detected in USA belonged to another subgroup with N397K+S82P in group 6B.

Conclusions

Vast majority of recent viruses isolated since September 2013 were antigenically closely related to A/California/7/2009 virus and a vaccine production virus A/California/7/2009 X-179A. Antiviral resistant viruses to oseltamivir and peramivir have increased since January 2014 in Sapporo city area. Those resistant viruses were antigenically similar to A/California/7/2009 virus

Antigen viruses for serology tests.

A(H3N2) viruses

Antigenic and Phylogenetic analyses:

- Total 62 and 45 viruses isolated since September 2013 were available for HI tests using ferret antisera raised against cell- and egg-propagated A/Texas/50/2012, respectively.
- All test viruses reacted within 4-fold different HI titer from the homologous titer of cell-propagated A/Texas/50/2012 antiserum and no virus with 8-fold reduced HI titer was observed, whereas 31% of test viruses showed over 8-fold reduced HI titer to egg-propagated A/Texas/50/2012 antiserum.
- Of those viruses, 74% exhibited 8-fold reduced HI titer from the homologous titer of X-223 (A/Texas/50-HGR) antiserum.
- All cell-propagated test viruses reacted within 4-fold different HI titer from the homologous titers of both antisera raised against cell- and egg-propagated A/New York/39/2012 viruses.
- A small number of test viruses (18 viruses) were subjected to HI tests using antisera of A/New York/39/2012 X-233 and A/New York/39/2012 X-233A. The A/New York/39/2012 X-233A antiserum well covered all test viruses, whereas 28% and 67% of tests viruses showed 8-fold and 4-fold reduced HI titers, respectively, against A/New York/39/2012 X-233 antiserum.
- The same test viruses were also subjected to HI tests using antisera raised against egg-propagated A/Almaty/2958/2013 wild type and NIB-85 (A/Almaty/2958/2013-HGR), which were kindly provided by NIMR. Fifty-six percent and 89 % of test viruses showed 8-fold reduced HI titer to A/Almaty/2958/2013 and NIB-85 antisera, respectively.
- In phylogenetic tree of HA gene, all test viruses fell into either recent major subgroup 3C.3 (51%) with T128A, R142G or subgroup 3C.2 (49%) with D489N. Phylogenetic tree of NA gene exhibited similar to that of HA gene.

Conclusions

- The majority of A(H3N2) viruses isolated since September 2013 was antigenically closely related to cell-grown A/Texas/50/2012virus, but they reacted poorly with A/Texas/50/2012 X-233 antiserum. Antisera against reference cell- and egg-propagated A/New York/39/2012 viruses covered recent test viruses well, while antisera against another egg-propagated reference virus A/Almaty/2958/2013 reacted poorly with recent viruses. No antiviral resistant virus to any of 4 NA inhibitors is found.

Antigen viruses for serology tests.
