(総合)研究報告書

化学物質の動物個体レベルの免疫毒性データ集積とそれに基づくMulti-ImmunoTox assay（MITA）による予測性試験法の確立と国際標準化　（　30210101　）

研究代表者　相場　節也
東北大学病院皮膚科教授

研究要旨
本課題においては，1)我々が開発した多項目免疫毒性評価系 Multi-ImmunoTox Assay (MITA)の免疫毒性化学物質評価法としての OECD テストガイドライン化に向けて国際 validation 試験ならびに 2)免疫毒性化学物質のデータベース作成を行ってきた。1）においては，MITA を構成する試験法の一つである IL-2 Luc assay に関して validation 試験、validation report の作成、peer review panel の評価を終了し 2020 年 11 月に SPSF を OECD に提出した。また IL-1 Luc assay に関しても phase I, phase II の validation 試験を終了し，2020 年海外からの liaison 委員を交えた validation management team (VMT) 会議の意見を参考にして validation report を作成し現在 liaison 委員からの意見をとりまとめている。一方，2）においては，上記 validation 試験にて評価した 50 化学物質，validation report 作成にあたり MITA にて評価した 60 化学物質に関して免疫毒性データを収集し免疫毒性データベースを構築した。また MITA の OECD テストガイドライン申請に向けて作成中の in vitro 免疫毒性試験法の現状と MITA の有用性に関する detailed review paper 作成に協力するとともに Section VIII にて MITA の概略を紹介した。

A．研究目的

研究背景：

アレルギー、自己免疫、免疫抑制など、人体に有害な影響を及ぼす化学物質による免疫毒性は、消費者、生産者はもとより厚生労働行政にとっても重大な課題となっている。現在、免疫毒性評価のゴールドスタンダードは動物実験であるが、数万ともいわれる化学物質を網羅的に評価、管理するには、*in vitro* high throughput 評価系や *in silico* 評価系の構築が不可欠である。そのためには、化学物質のアレルギー発症、易感染性など個体レベルの免疫毒性データの集積、その分子メカニズムの解析、さらにはそれらに基づいた adverse outcome pathway の作成が不可欠である。

我々は，平成18–22年NEDO「高機能簡易型有害性評価手法の開発」プロジェクトにおいて、化学物質の免疫毒性多項目評価システム(Multi-ImmunoToxicity assay；MITA)を構築し国内外の特許を取得している。

また平成24年度から平成26年度の3年間にわたる厚生労働科学研究費補助金事業「多色発光細胞を用いたhigh-throughput免疫毒性評価試験法の開発」においては、作用機序の明らかな種々の免疫抑制剤をMITAにより評価するなかで､化学物質免疫毒性評価におけるMITAのプロトコールを作成し、そのプロトコールに基づいて薬剤の免疫毒性評価を行った。その結果、代表的な免疫抑制剤であるデキサメサゾン(Dex)、サイクロスポリン(CyA)、タクロリムス（Tac）のT細胞とマクロファージ/樹状細胞に対する薬理効果をMITAが予測できることを明らかにした(Kimura et al. 2014)。

さらに平成27年度以降は、皮膚感作性試験法IL-8 Luc assayとMITAを組み合わせたmodified MITAを構築し60種類の化学物質を評価しdata setを作成した。また、そのdata setを基に化学物質のclusteringを行い、化学物質が免疫毒性のprofileの違いにより6つのグループに分類できることを示した(Kimura et al. 2018)。さらに、研究期間中にIL-8 Luc assayをOECDテストガイドライン化することができた(OECD442E) (OECD 2018)。

計画全体の目的：

1）既にOECD テストガイドライン(442E)に承認されている IL-8 Luc assay に加え、MITA を構成する IL-2 転写活性抑制評価試験(IL-2 Luciferase reporter assay; IL-2 Luc assay)と IL-1β転写活性抑制評価試験(IL-1 luciferase reporter assay; IL-1 Luc assay)の国際 validation study を行い、MITA の多項目免疫毒性評価系として OECD テストガイドライン化を目指す。

2)National Toxicology Program (NTP) の Dori Germolec 博士とミラノ大学の Emanuela Corsini 博士の協力を仰ぎ、NTP ならびに European Centre for Ecotoxicology and Toxicology of Chemicals のデータベースおよび PubMed を利用した文献検索に基づき免疫毒性のデーターベースを構築する。

3)上記データベースに基づき，MITA（図 1）を用いた化学物質の免疫毒性別クラスター分類における各クラスター免疫毒性の特性を明らかにする。

2018 年度

① 免疫毒性化学物質の毒性データーベースの構築
② MITA による免疫毒性 clustering の有用性の検討
③ IL-2転写活性抑制試験 (IL-2 Luc assay)に関するvalidation 試験の最終評価ならびにOECD提出用validation report作成
④ IL-1β転写活性抑制試験(IL-1 Luc assay)に関するPhase 0ならびにPhase I validation試験.
⑤ MITA を用いた免疫毒性評価系国際化へ向けての国際評価会議の kick-off meeting の開催

2019 年度

① IL-2転写活性抑制試験 (IL-2 Luc assay)に関するvalidation reportに対するpeer review panelによる評価とそれに対する対応

② IL-1β転写活性抑制試験(IL-1 Luc assay)に関する Phase I, Phase II validation 試験と Validation management teamによる最終評価
③ IL-1 Luc assay，IL-2 Luc assay により多種類の化学物質を評価し data set を作成する。
④ 免疫毒性化学物質のデータベース作成
⑤ MITA による免疫毒性 clustering の有用性の検討
⑥ MITA を用いた免疫毒性評価系国際化へ向けて，detailed review paper 作成を目的とした国際会議の開催

2020 年度
① IL-2転写活性抑制試験 (IL-2 Luc assay) のOECDテストガイドライン化に向けて, SPSFを提出し申請手続きを開始する。
② IL-1β転写活性抑制試験(IL-1 Luc assay)に関しては，validation試験を終了しVMT会議における意見を参考にvalidation reportを作成し，review panelによる評価を受ける。
③ MITA の有用性を確認する目的で，MITA による化学物質の評価を引き続き行い data set の拡充を図る。
④ MITA では評価できない，骨髄抑制，リンパ球増殖抑制をきたす化学物質を評価する IL-2 依存性細胞株を用いた試験法の開発を行う。
⑤ MITA の複数項目に関して効果発現最低濃度 (Lowest observed effect level ; LOWEL)を基にクラスター分類を行い, それにより化学物質の免疫毒性特性を明らかにする。
⑥ MITA の OECD テストガイドライン化にむけて in vitro 免疫毒性試験に関する detailed review paper の作成に協力する。
⑦ IL-8 Luc assay の特異性を改善するためのプロトコールの改変と OECD への修正ガイドラインの提案、ならびに THP-G8 細胞をより長期安定性を確保する目的での人工染色体を用いた新たな細胞株を樹立する。

B．研究方法

2018 年度

① IL-2 Luc assayに関するvalidation 試験の最終評価ならびにOECD提出用validation report作成

既にOECD テストガイドライン(442E)に承認されているIL-8 Luc assayに加え、MITAを構成するIL-2 Luc assay(国際validation phase I、IIが既に終了)の最終結果の総括とvalidation reportを作成する。

② IL-1 Luc assayに関するPhase 0ならびにPhase I validation試験

IL-1β 転写活性抑制評価系の国際 validation study を行い、MITA を多項目免疫毒性評価系として OECD テストガイドライン化を目指す。

③ 免疫毒性物質データベースの作成

National Toxicology Program (NTP)の Dori Germolec 博士とミラノ大学の Emanuela Corsini 博士の協力を仰ぎ、NTP ならびに European Centre for Ecotoxicology and Toxicology of Chemicals のデータベースおよび PubMed を利用した文献検索に基づき個体レベルの免疫毒性の網羅的データーベースを構築する。

④ MITA による免疫毒性 clustering の有用性の検討

一方、我々はこれまでに多項目免疫毒性評価系 (MITA)を開発し、その data set の作成、有用性の検討、国際標準化へむけての validation 等を行ってきた。その中で、60 種類の化学物質を MITA の複数項目に関して効果発現最低濃度 (Lowest observed effect level ; LOWEL)を基にクラスター分類することにより、免疫毒性物質が 6 種類のクラスターに分類できることを明らかにした。そこで、本課題では個体レベルの免疫毒性が明らかな化学物質を MITA による上記 6 種類のクラスターに分類し、クラスターごとの個体レベル免疫毒性発現の特性を明らかにする。

⑤ MITAを用いた免疫毒性評価系国際化へ向けての国際バリデーション実行委員会

平成30年度：2018年10月4-6日、神戸にて第5回国際バリデーション実行委員会会議を行った。

2019 年度

① IL-2 Luc assay validation reportに対するpeer review panelによるコメントとそれに対する対応

以下の会議を開催し，peer review panelからIL-2 Luc assay validation reportに対するコメントが提出され，それらに対応した。

1. 1st International peer review panel meeting on Multi-Immunotoxicity Test Assay (MITA))

2019年2月27-28日，品川

Peer review panel: Henk van Loveren, Haley LaNef Ford, Barbara Kaplan, Sang-Hyun Kim, Fujio Kayama, Takao Ashikaga,

Xingchao Geng
参加者：Hajime Kojima, Yutaka Kimura, Setsuya Aiba
2. 2nd International peer review panel meeting on Multi-Immunotoxicity Test Assay (MITA)(Webex)
2019年10月1日（火）
Peer review panel: Henk van Loveren, Haley Neff-LaFord, Barbara Kaplan, Fujio Kayama, Takao Ashikaga
参加者：Hajime Kojima, Yutaka Kimura, Setsuya Aiba
3. 3rd International peer review panel meeting on Multi-Immunotoxicity Test Assay (MITA) (Webex)
2019年11月18日（月）
Peer review panel: Henk van Loveren, Haley Neff-LaFord, Barbara Kaplan, Lin Shi, Xingchao Geng, Fujio Kayama, Takao Ashikaga
参加者：Hajime Kojima, Yutaka Kimura, Setsuya Aiba

② IL-1 Luc assay Phase IならびにPhase II validation試験

Phase I試験においては，国際バリデーション実行委員会 (VMT)にて選定された５化学物質をコード化し、東北大学，産業技術総合研究所バイオメディカル研究部門，産業技術総合研究所工学研究部門の参加3施設においてMulti-ImmunoTox Assay protocol for TGCHAC-A4 ver. 008Eにのっとり各物質3回繰り返し1セットの試験を３セットと実施した。
Phase II試験においては，VMTにより選定された20化学物質をコード化し、東北大学，産業技術総合研究所バイオメディカル研究部門，産業技術総合研究所工学研究部門の参加3施設においてMulti-ImmunoTox Assay protocol for TGCHAC-A4 ver. 008Eにのっとり各物質3回繰り返し1セットを実施した。
また，validation試験を遂行にあたり以下のVMT会議を行った。

1./ 2019年度第1回MITAバリデーション電話会議 （スカイプ）
2019年4月5日（金）9:30-11:00
参加者：大森、髙木、小島、足利、相場、木村
2./ 2019年度第2回MITAバリデーション電話会議 （スカイプ）
2019年5月2日（木）10:00-12:00
参加者：大森、小島、安野、中島、相場、木村、藤村
3./ Conference call for the MITA assay (Webex)
2019年6月26日（水）20:00-
参加者：Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Kojima, H.
4.5th meeting for the MITA Validation study
2020年1月30日（水）10：00-17：00
2020年1月31日（金）10：00-13：00
参加者：Corsini, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Kojima, H., Yasuno, R., Nakajima, Y.

③ IL-2 Luc assay, IL-1 Luc assayのdata set作成

Validation試験で評価した化学物質以外の化学物質もIL-1 Luc assay、IL-2 Luc assayにて評価し，これらの試験法のdata setを作成した。

④ 免疫毒性物質データベースの作成

National Toxicology Program (NTP) の Dori Germolec 博士とミラノ大学の Emanuela Corsini 博士の協力を仰ぎ、NTP ならびに European Centre for Ecotoxicology and Toxicology of Chemicals のデータベースおよびPubMed を利用した文献検索に基づき，validation 試験で用いた化学物質，data set に際して評価した化学物質を中心に免疫毒性データベースを構築した。

⑤ MITA による免疫毒性 clustering の有用性の検討

一方、我々はこれまでに 60 種類の化学物質を MITA の複数項目に関して効果発現最低濃度 (Lowest observed effect level ; LOWEL)を基にクラスター分類することにより、免疫毒性物質が 6 種類のクラスターに分類できることを明らかにした[3]。そこで、さらに改訂された上記データベースを参考に MITA によりクラスター分類を再検討する。

⑥ MITA を用いた免疫毒性評価系国際化へ向けての国際評価会議の開催

皮膚感作性試験法を除いては，in vitro 免疫毒性試験法は OECD テストガイドラインに存在しない。そこで，OECD 免疫毒性試験評価者の in vitro 免疫毒性評価系の現状と MITA の有用性の理解の促進を図る目的で，in vitro 免疫毒性評価法に関する detailed review paper (DRP)の作成を計画し以下の会議を開催した。

1.1st call for DRP in vitro immunotoxicity (Webex)
2019 年 9 月 18 日（水）、20 時
Emanuela Corsini, Erwin Roggen, Dori Germolec, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima, Steve Venti

2nd call for DRP in vitro immunotoxicity (Webex)

2019 年 10 月 28 日（水）、20 時
Emanuela Corsini, Erwin Roggen, Dori Germolec, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima, Steve Venti

3.3rd meeting for OECD DRP on in vitro immunotoxicity.
2020 年 1 月 28 日 9:00-17:30
2020 年 1 月 29 日 9:00-15:00
Emanuela Corsini, Dori Germolec, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima, Steve Venti

2020 年度

① SPSF提出に向けてIL-2 Luc assay validation reportを完成する。

以下の会議を行い、対応策を検討した。
2020 年 6 月 10 日
International peer review meeting on Multi-Immunotoxicity Test Assay (MITA) (Webex)
Emanuela Corsini, Dori Germolec, Haley Neff-LaFord, Henk van Loveren, Barbara Kaplan, Sang-Hyun Kim, Lin Shi, Xingchao Geng, Fujio Kayama, Takao Ashikaga, Setsuya Aiba, Yutaka Kimura, Hajime Kojima

2020 年 6 月 12 日
Conference call for the MITA assay validation study (Webex)
Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Nakajima, Y. Yasuno, R., Kojima, H.

2020 年 7 月 21 日
Conference call for the MITA assay validation study (Webex)
Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Nakajima, Y., Yasuno, R., Kojima, H.

2020 年 9 月 8 日
Conference call for the MITA assay validation study (Webex)

Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Nakajima, Y., Yasuno, R., Kojima, H.

2020 年 9 月 14 日
IL-2 Luc assay SPSF 提出についての打ち合わせ (Webex)
相場、木村（東北大）、足利、小島（国立衛研）

2020 年 10 月 29 日（東北大学皮膚科医局、仙台）
IL-2 Luc assay SPSF 提出についての打ち合わせ
足利（国立衛研）、相場、木村（東北大）

② IL-1 Luc assay validation report作成

前年度に行ったIL-1 Luc assay validation試験の結果をまとめ、Validation management team (VMT) 委員との検討を重ねvalidation reportを作成した。以下に、行った会議を記載する。
2020 年 6 月 10 日
International peer review meeting on Multi-Immunotoxicity Test Assay (MITA) (Webex)
Emanuela Corsini, Dori Germolec, Haley Neff-LaFord, Henk van Loveren, Barbara Kaplan, Sang-Hyun Kim, Lin Shi, Xingchao Geng, Fujio Kayama, Takao Ashikaga, Setsuya Aiba, Yutaka Kimura, Hajime Kojima

③ IL-1 Luc assay, IL-2 Luc assayのdata set作成

これまでの60のdata setに、IL-1 Luc assayにより特異的に評価できる3化学物質を加えて、IL-1 Luc assay, IL-2 Luc assayおよびIL-8 Luc assay に関して，それぞれの試験法の最終判定基準に則りdata setを作成する。

④ IL-1 Luc assay, IL-2 Luc assayのdata set作成

IL-1 Luc assay および IL-2 Luc assay の validation report 作成にあたり、validation 試験で用いた化学物質（各試験法あたり２５化学物質）および lead laboratory の in-house データベース 63 化学物質に関して免疫毒性情報を収集しデータベースを作成した。

⑤ 細胞分裂を抑制することにより免疫毒性をきたす化学物質スクリーニング系の開発

IL-2 Luc assayにはT細胞の細胞増殖や代謝活性を阻害する免疫抑制物質を検出できないという問題点が存在した。そこで、この問題を解決するため、２H4細胞を化学物質と24時間反応させた後に、PMAとIonomycinの混合物(PMA/Io)で刺激し化学物質で処理していないコントロールに比較してIL-2レポーター活性が維持または増加しているにも関わらずGAPDHプロモーター活性が低下、言い替えるとGAPDHで補正したIL-2レポーター活性が上昇することを指標にそのような免疫抑制物質を検出できないかを試みた。

[方法] Jurkat 由来の IL-2 レポーター細胞である 2H4 細胞を 96 ウェルプレートに播種し化学物質を加え 24 時間培養した。その後 PMA/Io で刺激し 6 時間培養後ルシフェラーゼ活性を測定した。
また開発した方法に関して、東北大学を lead laboratory として、国立医薬品食品衛生研究所安全性生物試験研究センター薬理部、国立研究開発法人産業技術総合研究所・健康工学研究部門、国立研究開発法人産業技術総合研究所・バイオメディカル研究部門、神戸大学医学部附属病院・臨床研究推進センターが validation management team を結成し、Liaison member に Emanuela Corsini (Milan Univ., Italy), Erwin L. Roggen (3Rs Management and Consulting ApS, Denmark), Dori Germolec (NTP/NIEHS, USA), Tomoaki Inoue (Chugai Pharmaceutical Co., Ltd.)を迎えて validation 試験を開始した。

⑥ MITA による免疫毒性 clustering の有用性の検討

一方、我々はこれまでに 60 種類の化学物質を MITA の複数項目に関して効果発現最低濃度 (Lowest observed effect level ; LOEL)を基にクラスター分類することにより、免疫毒性物質が 6 種類のクラスターに分類できることを明らかにした。そこで、さらに改訂された上記データベースを参考に MITA によりクラスター分類を再検討行った。

⑦ 試験管内免疫毒性試験法に関する detailed review paper 作成への参加協力

皮膚感作性試験法を除いては，in vitro 免疫毒性試験法は OECD テストガイドラインに存在しない。そこで，昨年度から OECD 免疫毒性試験評価者の in vitro 免疫毒性評価系の現状と MITA の有用性理解の促進を図る目的で， in vitro 免疫毒性評価法に関する detailed review paper (DRP) の作成が厚生労働科学研究法除菌小島肇班を中心に行われている。そこで DRP 作成に協力するとともに Section VIII にて MITA の概略を紹介する。関連して以下の会議に参加した。

2020 年 4 月 15 日
MITA DRP meeting (Webex)
Emanuela Corsini, Erwin Roggen, Dori Germolec, Haley Neff-LaFord, Barbara Kaplan, Setsuya Aiba, Takayuki Yoshimoto, Hajime Kojima, Steve Venti

2020 年 5 月 18 日
MITA DRP meeting (Webex)
Emanuela Corsini, Erwin Roggen, Dori Germolec, Haley Neff-LaFord, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima, Steve Venti

Expert group on immunotoxicity testing in OECD (Webex)
Setsuya Aiba　他

2020 年 10 月 14 日
MITA DRP meeting (Webex)
Emanuela Corsini, Erwin Roggen, Dori Germolec, Haley Neff-LaFord, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima

2020 年 11 月 12 日
MITA DRP meeting (Webex)
Emanuela Corsini, Erwin Roggen, Dori Germolec, Haley Neff-LaFord, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima

2020 年 12 月 14 日
MITA DRP meeting (Webex)
Emanuela Corsini, Erwin Roggen, Dori Germolec, Haley Neff-LaFord, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima

⑧ 修正IL-8 Luc assayの提案

厚労科研で開発したIL-8 Luc assay (OECD442E)では、培地に20 mg/mlの濃度で溶解しない化学物質のうち、IL-8 luciferase 活性を上昇させない物質は判定不能と分類される。そのため他の評価系に比べて判定できる化学物質が制限されるという欠点があった。そこで、その問題を改良する目的で、培地に溶解せずIL-8 luciferase 活性を上昇させない物質のうち、GAPDH luciferase活性を低下させる物質に関してGAPDH活性とPropidium iodide排除率等を比較検討した。また、併せてTHP-G8細胞の替わりとなるIL-1βプロモーター下流にSLGルシフェラーゼを含む人工染色体を導入したTHP-1由来細胞株の樹立を目指し実験を行った。

（倫理面への配慮）

ヒト、動物を対象にした研究は含まれていない。

C. 研究結果

2018 年度

① IL-2 Luc assayプロトコールならびにクライテリアの改訂

国際validation委員会にて，昨年度に策定されたクライテリア5を記載したプロトコール(Multi-Immuno Tox Assay protocol Ver.011E) Appendix 1(IL-2 Luc assay validation report draft Appendix)を作成した。このクライテリアを用いバリデーション研究を再評価したところPhase Iでは施設間再現性、施設内再現性はそれぞれ80.0 % (4/5)、86.7 % (13/15)であり、Phase IIでは施設間再現性が80 % (16/20)と良好な結果が得られた。そこで、IL-2 Luc assayのOECDガイドライン化を目指しバリデーションレポートを作成した。

② IL-1 Luc assayプロトコールならびにクライテリアの設定

昨年度、MITAとIL-8 Luc assayの結果を用い免疫毒性物質を６つのカテゴリーに分類する方法を提案した[2]。 既にIL-8 Luc assayは、OECD test guideline (442E)に承認され、またIL-2転写活性抑制評価系は、上述のように国際バリデーションphase I、IIが完了している。MITAのもう一つの構成因子として、THP-1細胞をベースとしたIL-1βレポーター細胞であるTHP-G1b細胞を用いた国際バリデーション試験を開始した。

1) IL-1 Luc assay Phase 0

国際バリデーション実行委員会にて選定したDapson, Diethanolamine, p-Nitroanilineについて参加3施設、産総研つくば、食薬センター、産総研高松においてMulti-Immuno Tox Assay protocol for TGCHAC-A4 ver. 007E (Appendix 3)にのっとり各物質3回繰り返し1セットの試験を2セット行った。%suppressionの閾値を20%と設定した場合、産総研つくば、産総研高松においてはリードラボと同様の結果が得られた。食薬センターについてはLPSによるFInSLG-LAの数値が得られない、再現性が得られない等の問題が認められた。食薬センターを含めた際の施設間再現性は83.3% (5/6)であった。

食薬センターについてはその後LPSによるFInSLG-LAの数値が得られない原因を検討し、FCSの非動化の方法、細胞へのLPSへの添加方法を再確認しアッセイしたところリードラボと同様の結果を得られた。

2) IL-1 Luc assay Phase 1

国際バリデーション実行委員会にて選定した５化学物質をコード化し、参加3施設、東北大学、産総研つくば、産総研高松においてMulti-Immuno Tox Assay protocol for TGCHAC-A4 ver. 008Eにのっとり各物質3回繰り返し1セットの試験を３セット実施した。次年度, Phase 1試験の結果をValidation management teamにて評価し今後の対応を決定する。

③ 免疫毒性物質データベース作成

免疫毒性分野では皮膚感作性試験におけるLLNAのようなゴールドスタンダードが存在せずpredictivity (accuracy)の算出ができない。っそこでValidation management team (VMT) のLiaison membersであるGermolec博士らによる化学物質の免疫機能に対する影響をまとめたレポート(添付資料１：Appendix 7)の提供をうけた。

2019 年度

① IL-2 Luc assay validation reportに対するpeer review panelによるコメントとそれに対する対応

今回IL-2 Luc assay validation reportを作成するにあたり，施設内，施設間再現生は試験開始前の目標値であった80%を達成した。しかし予測性に関しては，そもそも医薬品を除く多くの化学物質の免疫毒性評価が必ずしも定まっていないため確定できないでいた。またpeer review pane会議にて，IL-2 Luc assayは免疫毒性一般を評価する試験系ではなく, T細胞を一次標的として免疫毒性を惹起する免疫毒性物質の評価系であり，それを加味して予測性を決定するように指導された。そこで, 本試験において, NTPのLusterら(Luster et al. 1988; Luster et al. 1992a; Luster et al. 1993; Luster et al. 1992b)が51種類の化学物質の免疫毒性を動物実験を用いて評価した際の判定基準を参考にT細胞を標的とした化学物質の免疫毒性を評価する分類法を提案し，peer review panelにより了承された。これによりIL-2 Luc assayの予測性が決定した。それに基づきvalidation reportを修正し再度提出した。

我々が提出したvalidation reportに対して, International peer review panel meeting on Multi-Immunotoxicity Test Assay (MITA))から３度にわたり修正コメントを受け取り、それに対して適切に対応した。

② IL-1 Luc assay Phase Iならびに Phase II validation試験

IL-1 Luc assay Phase I試験を実施しwithin laboratory reproducibility, between laboratory reproducibility いずれも100%と

極めて良好な結果が得られた。この結果に関して以下の会議を開催した。
2019年度第1回MITAバリデーション電話会議　(スカイプ)
2019年4月5日（金）9:30-11:00
参加者：大森、髙木、小島、足利、相場、木村

2019年度第2回MITAバリデーション電話会議　(スカイプ)
2019年5月2日（木）10:00-12:00
参加者：大森、小島、安野、中島、相場、木村、藤村

第１回VMT会議 Conference call for the MITA assay (Webex)
2019年6月26日（水））20:00-
参加者：Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Kojima, H.
以上の会議で，予測性に関しての最終評価は定まっていないが，さらに20化学物質を用いて施設間再現性を評価するPhase II 試験を行う事が了承された。そこで，3施設でPhase II 試験を実施し2019年12月までに全ての施設が試験を完了した。そこで以下の会議で試験結果が検討された。その結果，施設間再現性はPhase II 試験のみの結果で80%，Phase I，II試験を統合した結果で84%となり，Phase Iの施設間再現性と共に試験開始前に想定していた採択基準をクリーアした。しかし，IL-1 Luc assayの再現性に関しては更に議論が必要と言うことになり，最終結論は次回のMVT会議に持ち越された。
第２回VMT会議
2020年1月31日（水））
会場：国立医薬品食品衛生研究所
参加者：Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Kojima, H.

③ IL-1 Luc assay, IL-2 Luc assayのdata set作成
IL-1 Luc assay, IL-2 Luc assayおよびIL-8 Luc assay に関して，それぞれの試験法の最終判定基準に則り現時点でのdata setを作成した。

④ 免疫毒性物質データベースの作成
IL-2 Luc assayのvalidationに用いた25化学物質，IL-2 Luc assayのdata set作成に用いた化学物質に関して免疫毒性データベースを作成した。（添付資料1:Appendix Table 1 and 2）データベースでは，化学物質の毒性データをin vivo、ex vivo、in vitroデータの3種類に分類した。具体的には、in vivo データの中には、免疫臓器の重量変化，遅延型過敏症，易感染性，移植腫瘍に対する抵抗性が、ex vivo データには、化学物質を投与された個体から採取した免疫担当細胞を用いてin vitroで化学物質の影響を評価するサイトカイン産生試験，T細胞依存性性抗体産生試験 (T-cell dependent antibody response; TDAR)が、in vitroデータには、個体から採取した免疫担当細胞に、in vitroで化学物質を加えてそのサイトカイン産生能の変化を評価するサイトカイン産生試験，T細胞の増殖能を評価する細胞増殖試験などを含めた。この作成に当たっては，National Toxicology Program (NTP)の協力を仰いだ。

⑤ MITA による免疫毒性 clustering の有用性の検討
あらたに得られたデータセットをもとに IL-8 Luc assay と組み合わせた MITA により化学物質の clustering を実施した。その結果を添付資料 13 に示す。しかし，IL-1 Luc assay，IL-2 Luc assay，IL-8 Luc assay の組み合わせでは，以前論文で報告した IL-2 Luc assay，IL-8 promoter assay，IL-8 Luc assay の組み合わせで行ったようには綺麗に clustering できなかった。また残念ながら、MITA では、一部の DNA 合成、細胞増殖抑制機序に基づく免疫毒性物質が評価できないことも明らかになった。

⑥ 試験管内免疫毒性試験法に関する detailed review paper の作成の参加協力
MITA のテストガイドライン化に向けて in vitro 免疫毒性評価法に関する detailed review paper (DRP)の作成に協力し以下の会議を開催した。
1.1st call for DRP in vitro immunotoxicity (Webex)
2019 年 9 月 18 日（水）、20 時
2. 2nd call for DRP in vitro immunotoxicity (Webex)
2019 年 10 月 28 日（水）、20 時
Emanuela Corsini, Erwin Roggen, Dori Germolec, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima, Steve Venti
上記会議において，以下の様な項目と執筆担当者が決定した。さらに下記の会議にて draft 案が提案され，それの修正を行った。
3.3rd meeting for OECD DRP on in vitro immunotoxicity.

2020 年 1 月 28 日 9:00-17:30
2020 年 1 月 29 日 9:00-15:00
Emanuela Corsini, Dori Germolec, Henk van Loveren, Barbara Kaplan, Setsuya Aiba, Yutaka Kimura, Takayuki Yoshimoto, Hajime Kojima, Steve Venti

2020 年度

①IL-2 Luc assay validation reportのSPSF提出

2020年11月13日に、改定したIL-2 Luc assay のvalidation report（添付資料１）ならびにSPSF（添付資料２）をWorking group of the National Coordinators for the Test Guidelines Program (OECD)に提出した。またvalidation試験の詳細に関しては、Toxicol in Vitroに報告した(Kimura et al. 2020)。

② IL-1 Luc assay validation report作成

昨年度に終了したIL-1 Luc assay Phase I, Phase II試験の結果ならびにlead laboratoryのin-houseデータを元にVMT委員と討議を重ねvalidation reportを完成させた（添付資料３）。現在、VMT委員と議論している。その結果を踏まえてpeer review panelの評価を受ける予定である。昨年度からに問題になっていたIL-1 Luc assayの予測性に関しては、Toll-like receptorやIL-1受容体の下流にある受容体のうちIRAK4、Myd88などIL-1 Luc assay以外には評価できないシグナル伝達物質が存在することを証明し、IL-1 Luc assayの有用性が確認できた。

③IL-1 Luc assay, IL-2 Luc assayのdata set作成

これまでの60のdata setに、IL-1 Luc assayにより特異的に評価できる3化学物質を加えて、IL-1 Luc assay, IL-2 Luc assayおよびIL-8 Luc assay に関して，それぞれの試験法の最終判定基準に則りdata setを作成した(添付資料４)。

④免疫毒性物質データベースの作成

IL-1 Luc assay作成の過程で、validationで用いた化学物質、data setに含まれる化学物質に関する免疫毒性データを収集しデータベースを作成した(添付資料３：Appendix 14 & 15)。データベースでは，化学物質の毒性データをin vivo、ex vivo、in vitroデータの3種類に分類した。具体的には、in vivo データの中には、免疫臓器の重量変化，遅延型過敏症，易感染性，移植腫瘍に対する抵抗性が、ex vivo データには、化学物質を投与された個体から採取した免疫担当細胞を用いてin vitroで化学物質の影響を評価するサイトカイン産生試験，T細胞依存性性抗体産生試験 (T-cell dependent antibody response; TDAR)が、in vitroデータには、個体から採取した免疫担当細胞に、in vitroで化学物質を加えてそのサイトカイン産生能の変化を評価するサイトカイン産生試験，T細胞の増殖能を評価する細胞増殖試験などを含めた。

⑤細胞分裂を抑制することにより免疫毒性をきたす化学物質スクリーニング系の開発

代表的なDNA合成阻害剤、代謝阻害剤であるgemcitabine hydrochloride、cytarabine、bleomycin sulfate、5-fluorouracilでは、従来のサイトカイン産生抑制を指標とするIL-2 Luc assayでは免疫抑制物質として検出されなかったが、24時間後の反応ではノーマライズしたIL-2レポーター活性の上昇、生存率の低下が認められた。一方dexamethasone、cyclosporine A、tacrolimusのサイトカイン産生抑制を機序とする免疫抑制物質では24時間の培養でもIL-2レポーター活性が抑制された。以上の結果からこの新しい方法 (IL-2 Luc leukocyte toxicity test (IL-2 Luc LTT))ではT細胞の細胞増殖や代謝活性を阻害する免疫抑制物質を検出しうることが示され、将来IL-2 Luc assayと組み合わせ幅広く免疫毒性物質をスクリーニングできる可能性が示唆された。
そこで添付のIL-2 Luc LTT protocolを作成し(添付資料５)、種々の免疫抑制剤、非免疫抑制剤を評価しIL-2 Luc LTT の免疫毒性試験法としての可能性を検討した。その結果、IL-2 Luc assay では評価できなかった細胞分裂、代謝活性に作用して免疫毒性を発現する化学物質を評価できることが分かり、現在国際的validation試験を行っている。また、本試験法に関しては、既に国際特許であるPCT出願を終了した。Validation試験のphase 1の結果を添付する(添付資料６)。Phase 1の結果は、VMTのliaison委員により承認された。

⑥ MITA による免疫毒性 clustering の有用性検討

あらたに得られたデータセットをもとに IL-8 Luc assay と組み合わせた MITA により化学物質の clustering を実施した。その結果を添付資料 13 に示す。しかし，IL-1 Luc assay, IL-2 Luc assay, IL-8 Luc assay の組み合わせでは，以前論文で報告した IL-2 Luc assay, IL-8 promoter assay, IL-8

Luc assay の組み合わせで行ったようには綺麗に clustering できなかった。また残念ながら、MITA では、一部の DNA 合成、細胞増殖抑制機序に基づく免疫毒性物質が評価できないことも明らかになった。

⑦ 試験管内免疫毒性試験法に関する detailed review paper の作成の参加協力

MITA のテストガイドライン化に向けて in vitro 免疫毒性評価法に関する DRP が小島班を中心に作成された。またそれに基づき、第 1 回の OECD expert group meeting が開催され、DRP に対するコメントがよせられている。上記 DRP 作成に協力するとともに Section VIII In vitro immunotoxicological assessments using the combination of cell lines の執筆を担当した。現在、それらのコメントに対し対応を検討している。

⑧ 修正IL-8 Luc assayの提案

厚労科研で開発したIL-8 Luc assay (OECD442E)では、培地に20 mg/mlの濃度で溶解しない化学物質のうち、IL-8 luciferase 活性を上昇させない物質は判定不能と分類される。そのため他の評価系に比べて判定できる化学物質が制限されるという欠点があった。そこで、その問題を改良する目的で、培地に溶解せずIL-8 luciferase 活性を上昇させない物質のうち、GAPDH luciferase活性を低下させる物質は、化学物質が培地中に溶解していることを証明し、陰性と判断することにした。具体的には、GAPDH活性とPropidium iodide排除率等を比較することで明らかにし、Arch Toxicolに掲載された「7」。そこで、改良IL-8 Luc assayに関してもSPSFを提出した(添付資料７)。THP-G8細胞の代替となる人工染色体技術を応用した新規IL-8レポーター細胞を樹立した（添付資料８）。

E. 考察

臨床的に使われる免疫抑制剤を除くと，化学物質の免疫毒性，特にヒトに対する免疫毒性の評価は定まっていない。確かに，個々の化学物質に関して，幾つかの免疫毒性評価試験を行った報告は多数存在するが，それらを総括して化学物質の免疫毒性の有無を総括した報告は我々が調べた限り存在しない。この問題は，免疫毒性試験法のvalidation試験を行う際に大きな障害となった。

そこで本課題において，化学物質の免疫毒性に関する文献資料を基に免疫毒性の有無を判定するクライテリアを提案した。幸い，本課題においてはvalidation試験と並行して行ってきた免疫毒性データベースが存在し，それをもとに分類することを検討した。その際に，Lusterら(Luster et al. 1988; Luster et al. 1992a; Luster et al. 1993; Luster et al. 1992b)が報告した免疫毒性分類法を参考にした。この方法では， 51種類の化学物質をマウスに投与し，その動物を種々の免疫毒性試験法で評価し免疫毒性の有無を判定するクライテリアを提案している。またそのクライテリアの判定結果とマウス感染実験から得られた易感染性の有無との相関も検討している。IL-2 Luc assayの予測性の評価においても，ほぼLusterらのクライテリアを参考に，作成した化学物質免疫毒性データベースをもとに評価化学物質の免疫毒性の有無を決定した。この妥当性は，peer review panelからも承認され、またToxicol in vitroにも掲載された(Kimura et al. 2020)。

これまで行ってきたMITAのvalidation試験の内、IL-2 Luc assayのPhase I、Phase II試験が終了した。これらの試験を通して、IL-2 Luc assayの施設間、施設内再現性が十分にOECDガイドライン化に必要な基準を満たしていることが明らかになった。予測性に関しては、上記化学物質の免疫毒性分類を参考にしつつ、IL-2 Luc assayが免疫毒性評価のなかでも、T細胞を標的にした免疫毒性を評価する試験であるを考慮することにした。具体的には、ex vivo、in vitroのT細胞由来サイトカイン産生能に影響を与える物質ないしは各化学物質のmode of actionにT細胞への作用が明記されている化学物質を陽性物質のリファレンスとした。

その結果、Phase I、IIをまとめたpredictivityは約67%となった。この値は、必ずしも十分な値ではないが、化学物質の免疫毒性の有無が必ずしも明確ではないこと、またT細胞を標的とした免疫毒性にもIL-2転写活性以外を標的とした作用が存在することは容易に想像できることから、他の免疫毒性評価系との組み合わせを前提にOECD TGに申請することにした。

同様にIL-1 Luc assayに関しても、validation試験を実施し、高い施設内、施設間再現生を示す結果が得られた。しかし、予測性に関しては、50%程度と満足のいく結果は得られなかった。加えて、陽性化学物質の大半がIL-2 Luc

assayの重複しており、IL-1 Luc assayの有用性が示せなかった。しかし、IRAK-4やTLR4阻害薬などIL-2転写に関わるシグナル経路に含まれない分子に対する阻害剤の効果を感度良く検出できることが示せた。

また、本研究課題のもう一つのテーマである化学物質の免疫毒性データの集積をNTPの協力を得て行った。IL-2 Luc assay、IL-1 Luc assayのvalidation試験に用いた化学物質、63種類のデータセットの化学物質に関して入手可能な免疫毒性データを網羅し、それらをin vivo，ex vivo、in vitroデータに分類し表にまとめた。その結果、各化学物質の大凡の免疫毒性profileが俯瞰可能となった。

免疫毒性クラスター解析では、IL-1 Luc assayとIL-2 Luc assayの組み合わせでは必ずしも有意義なクラスター分類は不可能であった。今後あらたな免疫毒性試験法との組み合わせを検討し、より有意義なクラスター分類を検討する必要性が明らかとなった。

最後に、本厚労科研の最終目標は、MITAを構築する免疫毒性試験のうちIL-2 Luc assayとIL-1 Luc assayを試験管内免疫毒性試験法としてOECD test guidelineとして承認を目指すことにあった。現在、IL-2 Luc assayに関しては、validation reportのpeer reviewが終了し、OECDのテストガイドライン化に向けて、Working Group of National Coordinators of the Test Guidelines Program (WNT) にSPSFを提出した。一方、IL-1 Luc assayは本厚労科研でvalidationから行いvalidation reportの作成が終了し、現在、validation management teamのexpertにより検討が行われている。また最終年度には、IL-2 Luc assayが判定できなかった細胞分裂、代謝活性に働き免疫抑制を示す免疫毒性物質の評価系を新たに開発し、現在validationを開始している。さらに、これまでの厚労科研で開発したIL-8 Luc assay (OECD TG 442E)の改良版のSPSFをWNTに提出した。またIL-1 Luc assay、IL-2 Luc assayの一連のvalidationを行うなかで、100近い化学物質に関する免疫毒性データベースを作成した。

E. 結論

本課題においては、当初の目標どおり、1)IL-2 Luc assay は OECD に SPSF を提出済み、2)IL-1 Luc assay に関しては Validation report を作成済み、3)約 100 の化学物質に関して免疫毒性に関するデータベースを作成した。4)免疫毒性物質の clustering に関しては、あらたに IL-2 Luc LTT を開発し、これらと IL-2 Luc assay、IL-1 Luc assay との組み合わせにより新しい知見を得ている。

1. Summary

The IL-2 luciferase reporter assay (IL-2 Luc assay) was developed as one of 3 luciferase reporter assays in the Multi-ImmunoTox assay (MITA), a high-throughput screening system that our group had developed to evaluate chemical immunotoxicity. Although our final long-term goal is to officially validate the MITA for within- and between- laboratory reproducibility and predictivity, in this study, we conducted the validation for IL-2 Luc assay as the initial step.

In the MITA, we used 3 stable lines of reporter cells transfected with luciferase genes under control of the IL-2, IFN-γ, IL-8, and IL-1β promoters: 2H4 cells derived from Jurkat cells containing stable luciferase green (SLG) regulated by the IL-2 promoter, stable luciferase orange (SLO) regulated by the IFN-γ promoter, and stable luciferase red (SLR) regulated by the GAPDH promoter; THP-G8 cells derived from THP-1 cells containing SLO regulated by the IL-8 promoter and SLR regulated by the GAPDH promoter; and THP-G1b cells derived from THP-1 cells containing SLG regulated by the IL-1β promoter and SLR regulated by the GAPDH promoter. We selected these 4 cytokines because IL-2 and IFN-γ are primarily produced by T cells (a type of adaptive immune cells), whereas IL-8 and IL-1β are primarily produced by monocytes and dendritic cells (types of innate immune cells).

Using these 3 cell lines, the MITA can evaluate the effects of chemicals on the IL-2 and IFN-γ luciferase activity of 2H4 cells stimulated with phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io), those on the IL-1β and IL-8 luciferase activity of THP-G1b and THP-G8 cells, respectively, stimulated by lipopolysaccharide (LPS).

In the validation study of the IL-2 Luc assay, the preliminary test trial, Phase 0, was performed by the participating laboratories following explicit explanations of the Multi-ImmunoTox Assay protocol Ver. 008.1E proposed by the lead laboratory, Tohoku University. Three laboratories participated in the Phase 0 study of the IL-2 Luc assay using 5 open labeled chemicals (2-aminoantracene, citral, chloroquine, dexamethasone and methyl mercuric chloride), in which they conducted 1 set composed of 3

experiments for each chemical. Most response patterns for the 5 chemicals were similar among the 3 laboratories, except for 2 early experiments conducted by the naïve laboratory. Based on these results, the Validation Management Team (VMT) judged that technical and protocol transfer of the IL-2 Luc assay is acceptable.

In the Phase I study, a total of 5 coded chemicals (4 T cell targeting and 1 non-T cell targeting) were evaluated by 3 experimental sets based on the Multi-ImmunoTox Assay protocol Ver. 011E made by the lead laboratory, Tohoku University. The average within-laboratory reproducibility was 86.7% (13/15). The between-laboratory reproducibility was 80.0% (4/5). The average predictivity was 93.3% (14/15).

In the Phase II study, between-laboratory reproducibility and predictivity using a total of 20 coded chemicals (13 T cell targeting, 6 non-T cell targeting, and 1 undetermined) were evaluated by 1 experiment set based on the Multi-ImmunoTox Assay protocol Ver. 009.1E. The between-laboratory reproducibility was 80% (16/20) and the average predictivity was 70.2% (40/57).

In the combined results of the Phase I and II studies, the average within-laboratory reproducibility was 86.7% (13/15). The between laboratory reproducibility was 80% (20/25). The average predictivity was 75.0% (54/72).

Although the within- and between-laboratory reproducibilities could satisfy the acceptance criteria for the validation study, the predictivity was below 80%. We considered several possible reasons for this unsatisfactory predictivity.

Since the 2H4 cell line used in the IL-2 Luc assay is derived from Jurkat cells, the IL-2 Luc assay cannot evaluate immunotoxic effects of immunosuppressive compounds whose mode of action is the inhibition of DNA synthesis leading to myelotoxicity. Thus, these chemicals should be outside the defined applicability domain for the assay. To overcome this limit, the IL-2 Luc assay requires combination with assays capable of detecting myelotoxicity, such as the conventional 28-day repeat dose toxicity test or *in vitro* myelotoxicity tests (Pessina et al., 2003). In addition, chemicals that need metabolic activation or poor water soluble need to be outside the applicability domain.

Even though these applicability domains are taken into consideration, the IL-2 Luc assay alone cannot cover all the effects of chemicals on human immune system. Therefore, it is indispensable to develop other *in vitro* systems to detect the effects of chemicals on different aspects of immune response. By accumulating and combining various approaches to detect chemical immunotoxicity, the *in vitro* assays can cover the effects of chemicals on the broad range of human immune system. The IL-2 Luc assay can be the first step.

2. Objective of the study

The objective of the present validation study was to determine the usefulness and limitations of the IL-2 Luc assay in MITA as a non-animal screening method to detect and assess the immunotoxicity of chemicals.

The specific objectives of the study were to establish:

1) “Transferability”, i.e., the extent to which a laboratory can adapt and easily implement the IL-2 reporter assay;

2) “Between or inter-laboratory reproducibility”, i.e., the extent to which results agree among different laboratories;

3) "Within or intra-laboratory reproducibility", i.e., the extent to which results agree in the same laboratory; and

4) “Predictivity”, i.e., the extent to which the *in vitro* results agree with the known immunological profiles of the chemicals.

3. Background

3-1. What is immunotoxicity?

A well-functioning immune system is essential for maintaining the integrity of an organism. Immune dysregulation can have serious adverse health consequences, ranging from reduced resistance to infection and neoplasia to allergic and autoimmune conditions. Environmental contaminants, food additives, and drugs can target the immune system, resulting in immune dysregulation. Accordingly, the potential for immunotoxicity, which is defined as the toxicological effects of xenobiotics on the function of the immune system, has raised serious concerns from the public as well as regulatory agencies. Currently, the assessment of chemical immunotoxicity relies mainly on animal models and assays that characterize immunosuppression and sensitization. However, animal studies have many drawbacks, such as high cost, ethical concerns, and questionable relevance to risk assessment for humans.

3-2. The current status of *in vitro* approaches to detect immunotoxicants

Now the worldwide vision is promoting alternative testing methods and assessment strategies to reduce the use of laboratory animals and, if possible, replace animals used in scientific studies (Adler et al., 2011). The workshop hosted by the European Centre for the Validation of Alternative Methods (ECVAM) in 2003 focused on state-of-the-art *in vitro* systems for evaluating immunotoxicity (Galbiati et al., 2010; Gennari et al., 2005; Lankveld et al., 2010). In the ECVAM workshop, a tiered approach was proposed. Since useful information can be obtained from regular 28-day general toxicity tests, pre-screening for direct immunotoxicity would begin with the evaluation of myelotoxicity in the proposed tiered approach (Corsini and Roggen, 2017). Compounds that are capable of damaging or destroying bone marrow will most likely have immunotoxic effects. If compounds are not potentially myelotoxic, they are tested for leukotoxicity. Compounds are then tested for immunotoxicity using various approaches such as the human whole-blood cytokine release assay (HWBCRA), lymphocyte proliferation assay, mixed lymphocyte reaction, NK cell assay, T cell–dependent antibody response, dendritic cell maturation assay, and fluorescent cell chip (FCP) assay. Among these assays, the HWBCRA has undergone formal pre-validation, although other techniques are being examined or have been examined in a rigorous pre-validation effort by the ECVAM and other groups. (Fig. 1) However, these assays require fresh rodent or human immune cells, in conflict with animal protection goals. The need for primary cells may decrease reproducibility and makes the assay unsuitable for high-throughput approaches

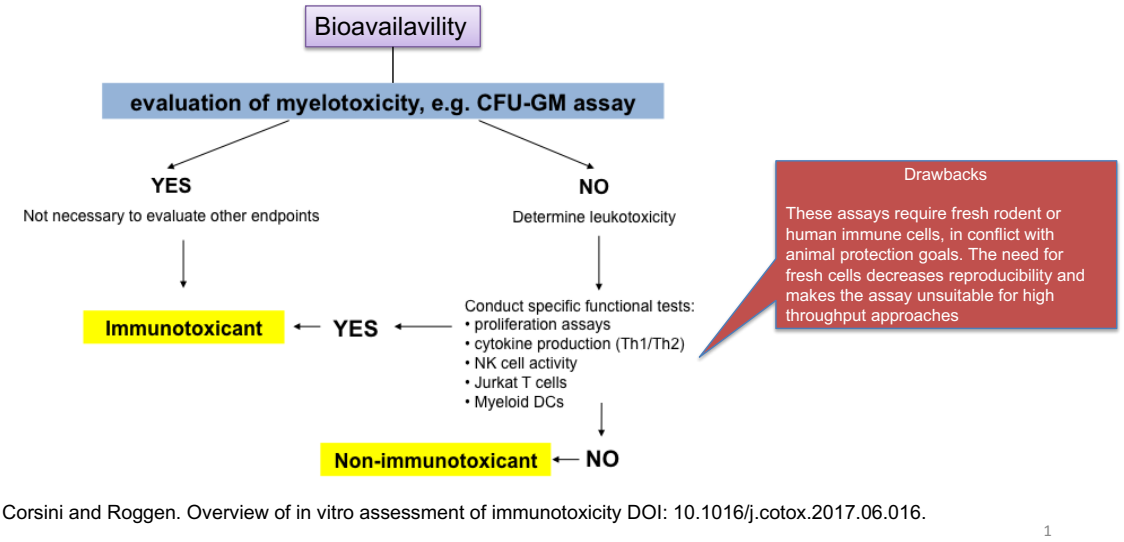

Fig. 1. Decision tree approach for *in vitro* assessment of chemical-induced immunosuppression.

3-3. *In vitro* immunotoxicity tests in principle should evaluate effects on both innate and acquired immunity

The immune system comprises innate and adaptive immunity (Fig. 2). Both arms of the immune response function differently and are driven by different populations of cells. In innate immunity, pathogens are recognized through various pattern recognition molecules, such as C-type lectin receptors, toll-like receptors, nod-like receptors, and retinoic acid–inducible gene-I (RIG-I)-like receptors. In addition, a variety of different cells are involved in this type of response, including neutrophils and other types of granulocytes, macrophages, natural killer (NK) cells, innate lymphoid cells, and mast cells. Adaptive immune responses involve specific antigen receptors encoded by rearranged genes, and T cells and B cells play critical roles in these responses.

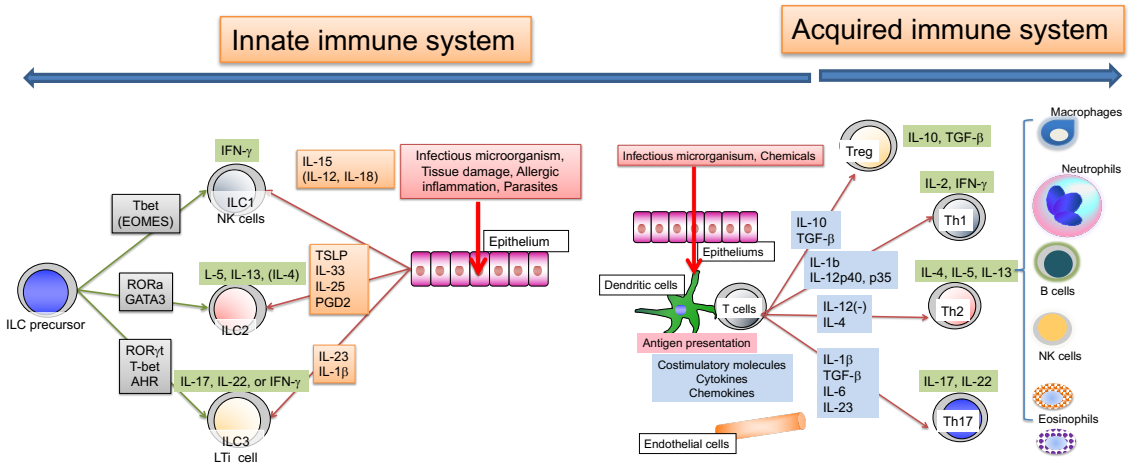

Fig2. Schematic representation of the innate immune system and acquired immune system.

Macrophages and dendritic cells (DCs), which act as antigen-presenting cells (APCs), link the innate and adaptive immune responses because they can present antigens to T lymphocytes in the context of major histocompatibility complex (MHC) class I or II molecules and stimulate their proliferation and effector functions after being stimulated via pathogen recognition receptors (Fig. 3). To induce optimal immune responses to various pathogens and minimize autoreactivity, innate and adaptive immune cells produce a vast array of cytokines, chemokines, and chemical mediators and present the molecules required for direct cell-cell interaction on their surface. A variety of intracellular signaling pathways also play roles in innate and adaptive immune responses.

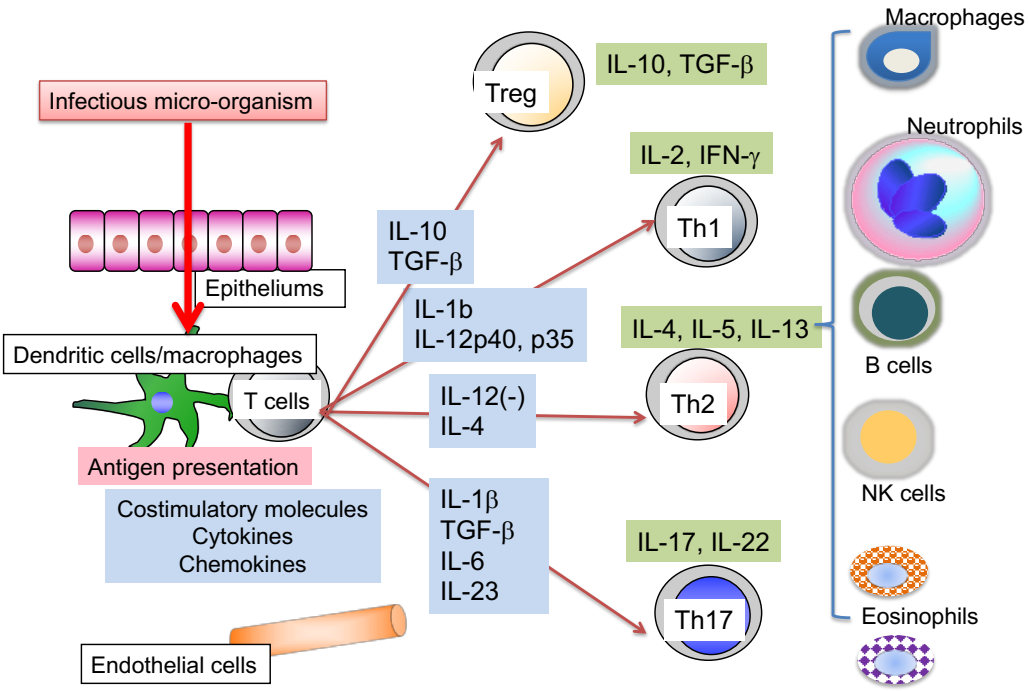

Fig. 3. Dendritic cells link the innate immune response to the acquired immune response.

Theoretically, chemicals can affect the immune system by targeting either the innate immune system or the acquired immune system (Fig. 2 and Fig. 3). Therefore, novel *in vitro* test methods are needed to adequately assess the immunotoxic effects of chemicals on both arms of immune system.

3-4. Mechanism for the induction of immunotoxicity by chemicals

Given the complexity of the immune system, it is unlikely that a single *in vitro* method will be able to detect all immunotoxicants. The mechanisms underlying the immunotoxicity of chemicals can be classified into 3 main categories: 1) killing of immune cells caused by bone marrow toxicity, 2) interference with general or immune-specific signaling leading to changes in the expression of cell surface molecules, cytokines or chemokine production, cell differentiation, and activation, and 3) binding to proteins forming complete antigens or exposing cryptic self-proteins (Fig. 4).

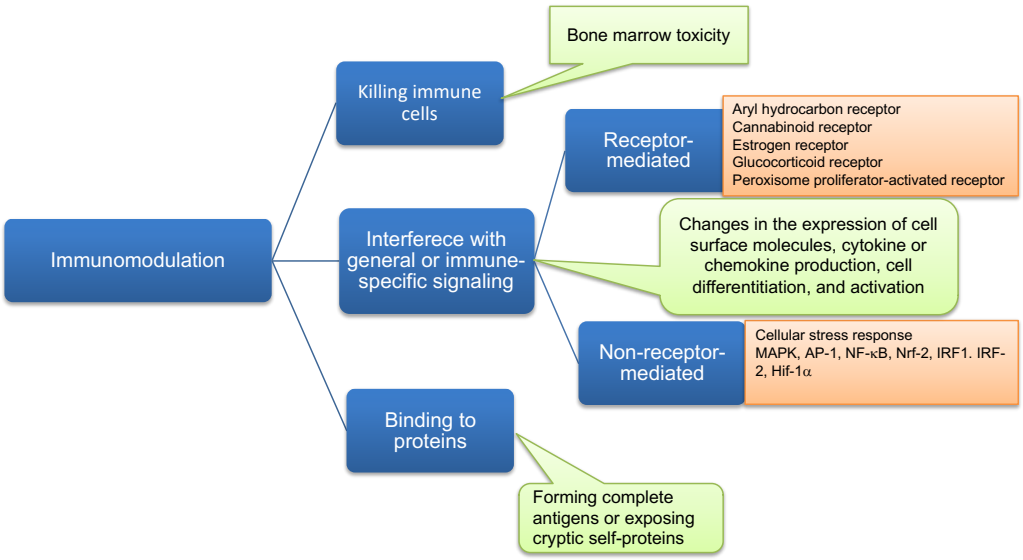

Fig. 4. Main mechanisms of immunotoxicity

Chemicals can interfere with immune-related cell signaling through receptor-mediated pathways using xenobiotic receptors such as the aryl hydrocarbon receptor (AhR), constitutive androstane receptor (CAR), or pregnane X receptor (PXR) (Elentner et al., 2018; Hidaka et al., 2017), cannabinoid receptor, estrogen receptor, glucocorticoid receptor or peroxisome proliferator-activated receptor or through non-receptor-mediated ways. Without specific receptors, it has been demonstrated that so-called cellular stress response can cause immunotoxicity (Fulda et al., 2010; Kultz, 2005). In essence, as long as stress stimulus does not cross a certain threshold, a cell can cope and survive by mounting an appropriate protective response. Conversely, the failure to activate or maintain a protective response (e.g., when the stressor is too strong) results in activation of stress signaling cascades that eventually activate cell death pathways. Depending on the type of stress and its severity, a cell's response can be manifold. However, most cellular protective responses induced by chemicals can be classified into one of several

categories, such as heat shock, unfolded protein, DNA damage, and oxidative stress responses, in addition to the response to danger signals (Gallucci and Matzinger, 2001). These responses are independent of the chemical species (Fig. 5). In addition, these cellular stress responses can affect immune function because they share the same cellular signaling pathways, e.g., MAP kinase, NF-κB, and mTOR, used by the immune response (Milisav, 2011). Indeed, although sensitizers that induce allergic contact hypersensitivity include numerous compounds with different molecular structures, it has become clear that their ability to sensitize is based simply on their reactivity to cysteine residues, which induces a response to oxidative stress (Sasaki and Aiba, 2007). Therefore, although it is assumed that there may be many chemicals with the potential to produce immunotoxicity, only a limited number of assay systems may be required to detect their effects.

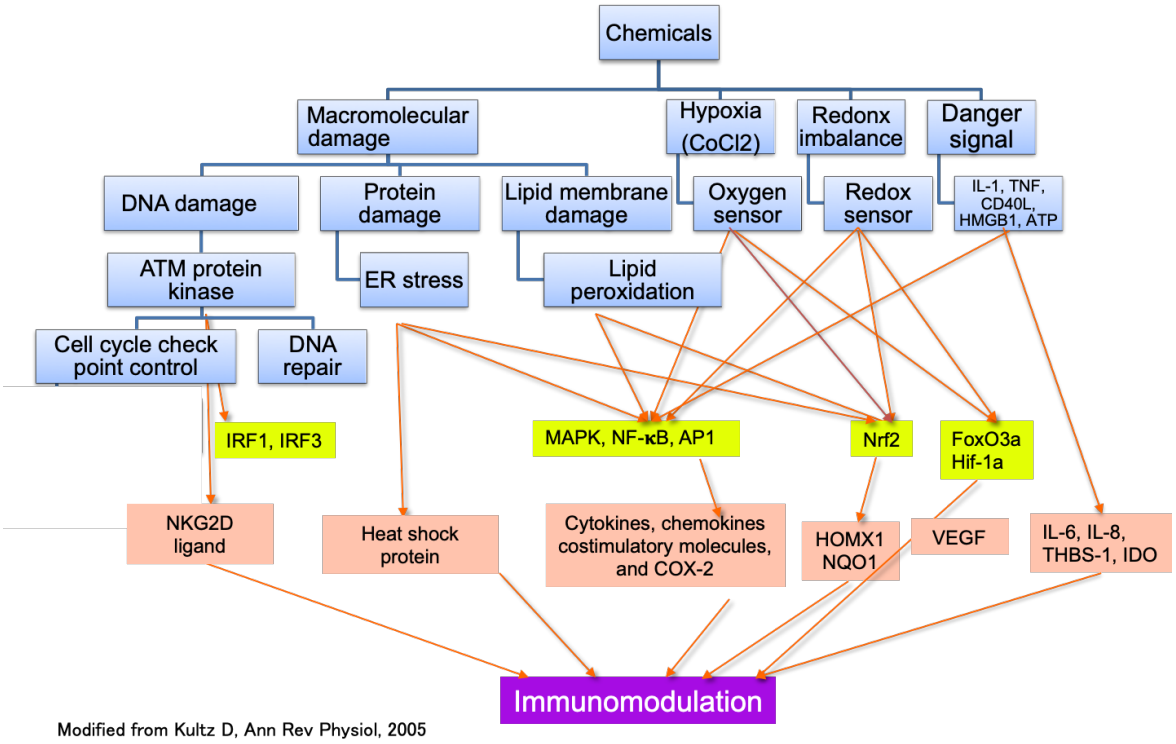

Fig. 5. Cellular stress response and danger signals.

3-5. Multi-ImmunoTox assay (MITA)

Our group developed a high-throughput screening system to evaluate chemical immunotoxicity. We first established 3 stable reporter cell lines transfected with luciferase genes under control of the IL-2, IFN-γ, IL-8, and IL-1β promoters: 2H4 cells derived from Jurkat cells containing stable luciferase green (SLG) regulated by the IL-2 promoter, stable luciferase orange (SLO) regulated by the IFN-γ promoter, and stable luciferase red (SLR) regulated by the GAPDH promoter (Saito et al., 2011); THP-G8 cells derived from THP-1 cells containing SLO regulated by the IL-8 promoter and SLR regulated by GAPDH promoter (Takahashi et al., 2011); and THP-G1b cells derived from THP-1 cells containing SLG regulated by the IL-1β promoter and SLR by the GAPDH promoter (Kimura et al., 2014). These 4 cytokines were selected because IL-2 and IFN-γ are primarily produced by T cells (adaptive immune cells), whereas IL-8 and IL-1β are primarily produced by monocytes and dendritic cells (innate immune cells). Using these 3 cell lines, we established the Multi-ImmunoTox assay (MITA). This assay identifies the effects of chemicals on the IL-2 and IFN-γ luciferase activity in 2H4 cells in the presence of the stimulants phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io), and on the IL-1β and IL-8 luciferase activities in THP-G1b and THP-G8 cells, respectively, in the presence of the stimulant lipopolysaccharide (LPS) (Fig. 6).

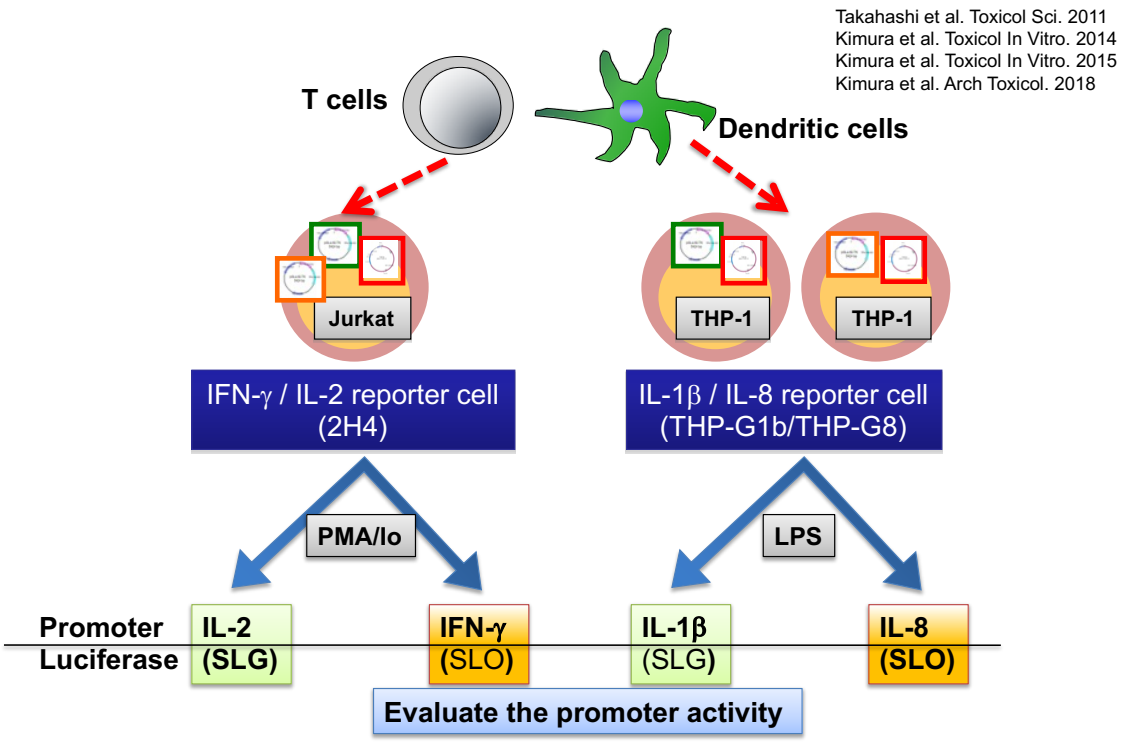

Fig. 6. The Muti-ImmunoTox assay (MITA)

3-6. The luciferase activities of the three MITA cell lines correspond with mRNA expression in the wild type cell lines or in human whole blood cells when stimulated with PMA/Io or LPS in the presence of 3 representative immunosuppressive drugs

After establishing the MITA, we first compared the effects of dexamethasone, cyclosporine, and tacrolimus on the 3 MITA cell lines with those on mRNA expression in the wild type cell lines or in human whole-blood cells stimulated with PMA/Io or LPS. The results confirmed that the MITA correctly reflects changes in mRNA expression in the mother cell lines and whole-blood cells (Kimura et al., 2014).

3-7. The MITA can evaluate the immunotoxicity profiles of well-known immunosuppressive drugs

We next evaluated the performance of the MITA by examining immunosuppressive or immunomodulatory drugs with well-known clinical effects on the human immune system (Kimura et al., 2014). The results obtained with immunosuppressive drugs classified by their principal mechanism of action are shown in Table 1, in which the classification of drugs is based on the review by Allison (Allison, 2000).

The MITA demonstrated that dexamethasone (Dex) significantly suppressed IL-2, IL-1β, and IL-8 reporter activities, while cyclosporine A (CyA) and tacrolimus (Tac) suppressed IL-2 and IFN-γ reporter activities but had no effect on IL-1β and IL-8 reporter activities. However, the MITA could not detect the immunosuppressive effects of the alkylating agent cyclophosphamide, of the inhibitors of de novo purine synthesis azathioprine (AZ), mycophenolic acid (MPA) and mizoribine (MZR), and of the inhibitor of pyrimidine and purine synthesis, methotrexate (MT). These data suggest that the MITA correctly evaluates the effects of chemicals on cytokine expression but cannot detect immunotoxicity associated with the inhibition of DNA synthesis and cell division. This drawback has also been reported for other assays, such as the human whole-blood cytokine release assay (HWBCRA) (Langezaal et al., 2002) and the FCP assay (Wagner et al., 2006). On the other hand, the MITA has the advantage that it can discriminate the effects of chemicals on T cells from those on macrophages/dendritic cells.

Table 1. The MITA can detect immunosuppressive effects of representative immunosuppressive drugs

Principal mechanism of action	Drugs	The effects of transcriptional activity			
		IL-2	IFN-γ	IL-1β	IL-8
Immunosuppressing drugs					
Regulation of gene expression	Dexamethasone (Dex)	S	N	S	S
Kinase and phosphatase inhibitors	Cyclosporin A (CyA)	S	S	N	N
	Tacrolimus (Tac)	S	S	N	N
	Rapamycin (RPM)	A	N	N	N
Alkylation	Cyclophosphamide (CP)	N	N	N	N
Inhibition of de novo purine synthesis	Azathioprine (AZ)	N	N	N	N
	Mycophenolic acid (MPA)	A	A	N	N
	Mizoribine (MZR)	N	N	A	A
Inhibition of pyrimidine and purine synthesis	Methotrexate (MTX)	N	A	N	N
Off-label immunosuppressing drugs					
	Sulfasalazine (SASP)	S	S	S	S
	Colchicine	S	N	A	N
	Chloroquine (CQ)	S	N	N	N
	Minocycline (MC)	S	S	N	N
	Nicotinamide (NA)	S	N	S	S
Non-immunomodulatory drugs					
	Acetaminophen (AA)	N	N	N	N
	Digoxin	S	S	N	N
	Warfarin	N	N	S	S

Kimura et al. Toxicol in Vitro 28: 759-769, 2014

*S and A indicates that drugs showed statistically significant suppression in triplicate experiments for each parameter, while N indicates that drugs did not show significant effects.

3-8. The process of validation of the MITA

Although our final goal is to officially validate the MITA for within- and between-laboratory reproducibility and predictivity, in this study, we conducted the validation study for the IL-2 Luc assay as the initial step. Since 2H4 cells used in this validation study is derived from Jurkat cells that contain SLG regulated by the IL-2 promoter, SLO

regulated by the IFN-γ promoter, and SLR regulated by the GAPDH promoter (Saito et al., 2011), this cell line can simultaneously evaluate the effects of chemicals on IL-2 and IFN-γ transcription. However, our previous study demonstrated the significant correlation between the Lowest Observed Effect Levels (LOELs) for the effects of chemicals on the IL-2 luciferase assay and those on the IFN-γ luciferase assay (Kimura et al, 2014). Therefore, we decided to conduct the validation study of only IL-2 Luc assay. Recently, the process of this validation study has been published (Kimura et al., 2020)

3-9. The proposed Adverse Outcome Pathway (AOP) of chemicals that affect IL-2 transcription

Immune dysregulation may have serious impacts on human health, ranging from reduced resistance to infection and neoplasia to allergic and autoimmune conditions. Pivotal immune elements of these diseases are the development of antigen-specific effector T-helper type (Th2) cells, Th1 cells, Th17 cells, and regulatory T cells (Treg cells) that are associated with clinical features and disease progression. Consequently, identifying the immunotoxicity of chemicals requires clarifying their effects on the development of these T cells (reviewed by (Kaiko et al., 2008)).

IL-2 exerts pleiotropic actions on CD4+ T cell differentiation via its modulation of cytokine receptor expression. IL-2 promotes Th1 differentiation by inducing IL-12Rb2 (and IL-12Rb1), promotes Th2 differentiation by inducing IL-4Ra, inhibits Th17 differentiation by inhibiting gp130 (and IL-6Ra), and drives Treg differentiation by inducing IL-2Ra. IL-2 also potently represses IL-7Ra, which decreases survival signals that normally promote cell survival and memory cell development (reviewed by (Liao et al., 2011)). It is therefore conceivable that chemicals that affect IL-2 release by T cells could significantly impact immune function; consequently, we focused on the regulation of IL-2 transcription and attempted to construct an AOP with transcriptional dysregulation of IL-2 as a central key event.

IL-2 mRNA is transcribed after T cell receptor stimulation. Therefore, chemicals that affect any pathway leading to IL-2 transcription after T cell activation can induce dysregulation of IL-2 mRNA and protein expression by T cells. In antigen presentation, T cells are stimulated by T cell receptor (TCR) with co-receptor CD4 or CD8 and CD28. The TCR with CD4 or CD8 recognizes the major histocompatibility complex (MHC)–peptide complex, which results in activation of the SRC kinase Lck and subsequent phosphorylation of immunoglobulin family tyrosine (Y)-based activation motifs (ITAMs) in the CD3 complex (Y-p). This leads to recruitment and phosphorylation of ζ-chain-associated protein (ZAP70), which phosphorylates adaptor proteins, resulting in activation of phospholipase Cγ1 (PLCγ1) and the guanine triphosphatase RAC. PLCγ, in turn, promotes Ca^{2+} mobilization and RAS activation. The combination of these upstream events leads, by complex signaling cascades, to activation of the mitogen-activated protein (MAP) kinases: extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK), and p38, as well as phosphatidylinositol 3-kinase (PI3K) and protein kinase B (PKB/Akt). Together, these signals promote different events, including the activation of transcription factors, which result in gene expression and, presumably, T-cell function. On the other hand, CD28 might associate, in its unphosphorylated state, with the serine/threonine phosphatase protein phosphatase 2A (PP2A). Upon T-cell stimulation, CD28 undergoes phosphorylation on its intracellular tyrosine residues (Y), presumably resulting in dissociation from PP2A and recruitment of phosphatidylinositol 3-kinase (PI3K) and growth-factor-receptor-bound protein 2 (GRB2). Activation of PI3K, which induces phosphorylation of phosphatidylinositol (PI) into phosphatidylinositol 3-phosphate (PIP3), might promote activation of protein kinase B (PKB/Akt), followed by activation of nuclear factor-κB (NF-κB), resulting in BCL-XL upregulation that favors T-cell survival. Akt activation might also promote interleukin-2 (IL-2) production. PI3K is negatively regulated by phosphatase and tensin homologue (PTEN). The carboxy-

terminal proline (P)-rich region might promote IL-2 production and proliferation, perhaps by recruiting and activating Lck (reviewed by (Alegre et al., 2001)).

Many chemicals have been reported to affect IL-2 transcription or production. Any component of these signaling cascades can be a potential target of these chemicals, but the mechanism by which they affect IL-2 transcription or production remains largely unknown.

Based on recent advances in immunology, we tentatively propose the following AOP for immunosuppression focusing on IL-2 transcription. Figure 7 shows the AOP with representative chemicals that affect IL-2 transcription. From 2001 to 2017, 54 chemicals were reported to augment IL-2 gene or protein expression in human and 60 chemicals had this effect in mice, while 65 chemicals in human and 47 chemicals in mice were reported to decrease IL-2 gene or protein expression, as determined by a PubMed search.

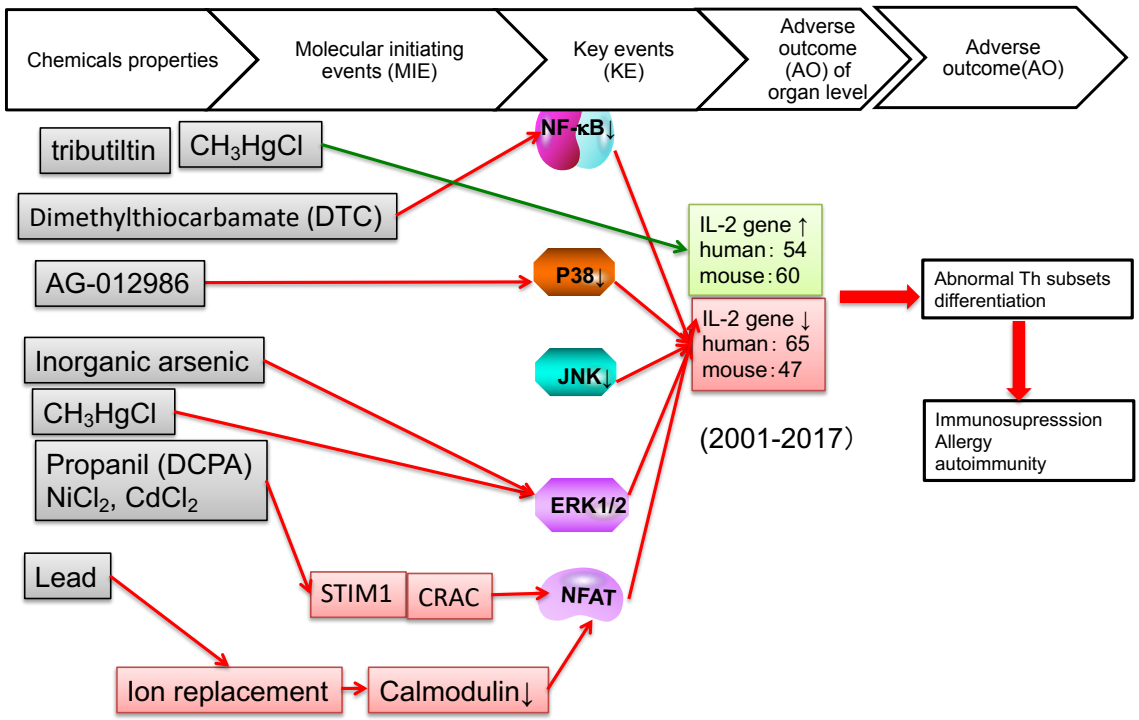

Fig. 7. The proposed AOP for dysregulation of Th subset differentiation triggered by disrupted IL-2 transcription.

4. Test method and modification

4-1. IL-2 reporter cell, 2H4

The Jurkat human acute T lymphoblastic leukemia cell line kindly provided by Professor Kazuo Sugamura, Department of Microbiology, Tohoku University School of Medicine, was cultured in RPMI-1640 (Sigma-Aldrich, St. Louis, MO) containing Antibiotic-Antimycotic (Invitrogen) and 10% Hyclone^{TM} fetal calf serum (Thermo Fisher Scientific, Waltham, MA) (Jurkat growth medium) at 37°C with 5% CO_2. The luciferase reporter assay system was constructed using 3 luciferases that emit green light (Stable luciferase green; SLG), orange light (Stable luciferase orange; SLO), and red light (Stable luciferase red; SLR) using a single substrate. Namely, we constructed three luciferase vectors, pSLG-test/Hyg^r, pSLO-test/Neo^r, and pSLR-test/Pur^r, by ligating the *Bam*HI/*Sac*I site of resistant gene vectors containing one of three resistant genes, hygromycin (SLG), neomycin (SLO) or puromycin (SLR), SV40 promoter, and HSVtk polyA into luciferase gene vectors, pSLG-test, pSLO-test and pSLR-test (Toyobo, Osaka, Japan), respectively. The activities of the luciferases can be measured simultaneously and quantitatively with optical filters. This system can rapidly and easily monitor the expression of multiple genes (Nakajima et al., 2005; Noguchi et al., 2008).

4-2. Chemical treatment of 2H4 cells and measurement of luciferase activity

Based on previous reports(Saito et al., 2011; Takahashi et al., 2011), 2H4 cells (2×10^5 cells/50 μl/well) in 96-well black plates (Greiner Bio-One GmbH, Frickenhausen, Germany) were pretreated with different concentrations of individual chemicals for 1 h. The 2H4 cells were then stimulated with 25 nM PMA and 1 μM ionomycin (PMA/Io) for 6 h. Three luciferase activities (SLG luciferase activity (SLG-LA), SLO luciferase activity (SLO-LA), and SLR luciferase activity (SLR-LA)) were simultaneously determined using a microplate-type luminometer with a multi-color detection system (Phelios; Atto Co., Tokyo, Japan) and Tripluc luciferase assay reagent (TOYOBO Co., Ltd., Osaka, Japan) according to the manufacturers' instructions. Use of

the 2H4 cell line enabled measurement of SLO-LA driven by the IL-2 promoter (IL2LA), SLG-LA driven by the INF-γ promoter (IFNLA), and SLR-LA driven by GAPDH (GAPLA) in 2H4 cells. In this validation study, however, we just used the IL2LA and GAPLA and ignored IFNLA because there was a significant correlation between LOELs for the effects on the IL2LA and those on the IFNLA (Kimura et al., 2018). We accounted for the variation in cell number and cell viability after chemical treatment by normalizing the data for IL2LA (nIL2LA) by dividing IL2LA with GAPLA in the 2H4 cells. In addition, we calculated % suppression, % augmentation, and Inh-GAPLA as follows:

% suppression = (nIL2LA of 2H4 cells treated with chemicals/nIL2LA of non-treated 2H4 cells) x 100;

% augmentation = (1-(nIL2LA of 2H4 cells treated with chemicals/nIL2LA of non-treated 2H4 cells)) x 100;

Inh-GAPLA = GAPLA of 2H4 cells treated with chemicals/GAPLA of untreated cells.

Definitions of these terms are provided in Table 2.

Table 2. Definition of the parameters in the IL-2 Luc assay.

Abbreviations	Definition
IL-2 Luc assay	IL-2 luciferase assay
GAPLA	SLR luciferase activity reflecting GAPDH promoter activity
IL2LA	SLO luciferase activity reflecting IL-2 promoter activity of 2H4 cells
IFNLA	SLG luciferase activity reflecting IFN-γ promoter activity of 2H4 cells
nIL2LA	IL2LA/GALA of 2H4 cells
nIFNLA	IFNLA/GALA of 2H4 cells
% suppression	(nIL2LA of 2H4 cells treated with chemicals/ nIL2LA of non-treated 2H4 cells) x 100
% augmentation	(1-(nIL2LA of 2H4 cells treated with chemicals/ nIL2LA of non-treated 2H4 cells)) x 100
CV05	The lowest concentration of the chemical at which Inh-GAPLA becomes < 0.05.
Inh-GAPLA	GAPLA of 2H4 cells treated with chemicals /GAPLA of untreated cells.

4-3. Criteria to determine the effects of chemicals on T cells

During the validation study, we modified the criteria to determine the effects of chemicals on T cells to determine the criteria for the MITA.

We used the following Criteria 1 in our first publication describing the MITA. Three independent experiments were conducted for each chemical. For each experiment, a one-way ANOVA test followed by Dunnett's post hoc test was used to evaluate statistical significance. If chemicals showed statistically significant immunosuppression or immunostimulation in 3 experiments, they were judged as immunosuppressive or immunostimulatory drugs, respectively. If chemicals showed statistically significant immunosuppression or immunostimulation in only 2

independent experiments, they were judged as potential immunosuppressive or immunostimulatory drugs, respectively. If not, they were judged as ineffective. Then, for potential immunosuppressive or immunostimulatory drugs, we selected their percent suppression or percent augmentation (negative percent suppression) in 3 experiments that showed the most significant change, calculated their percent suppression or percent augmentation, and statistically compared suppression or augmentation by the chemicals with that of the vehicle control in 3 different experiments by the Student's t-test. Only when chemicals demonstrated statistical significance were they judged as immunosuppressive or immunostimulatory, respectively(Kimura et al., 2014).

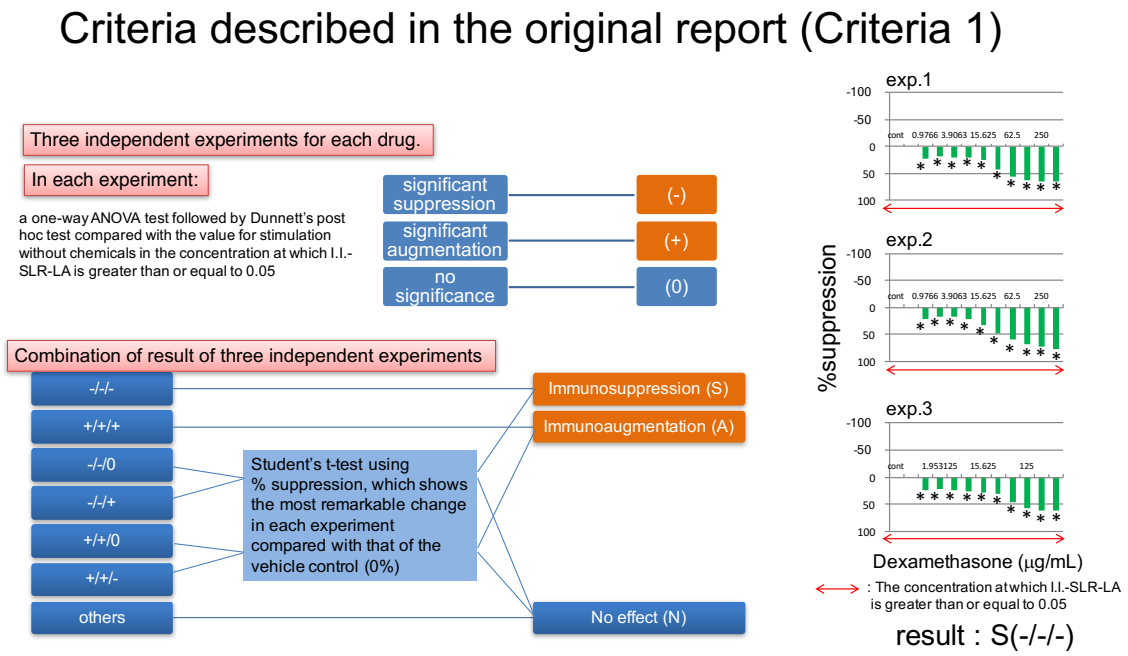

Fig.8 Criteria 1 in the original report

After the pre-validation study, in addition to the original criteria (Criteria 1, Fig.8), two new criteria were proposed by the statistician (Criteria 2, Criteria 3). These 3 criteria were used temporarily and one of these criteria would be adopted after the Phase I validation study.

4-4. Bioluminescence system

In a typical dual-reporter assay, firefly luciferase from *Photinus pyralis* (FLuc) is used as the experimental reporter and Renilla luciferase is used as the internal control reporter. This internal control reporter connects to a constitutively expressed promoter, such as the herpes simplex virus thymidine kinase promoter, cytomegalovirus (CMV) immediate-early promoter, or simian virus 40 (SV40) promoter. This assay system is commercialized as a Dual-Luciferase Reporter Assay System by Promega Corporation. In this system, both luciferase activities are measured sequentially from single extracts on the basis of their bioluminescent substrate specificity. Firefly luciferase activity is measured first by adding firefly D-luciferin, and then Renilla luciferase activity is measured by adding coelenterazine (another name for Renilla luciferin), with concomitant quenching of firefly luciferase luminescence. Finally, firefly luciferase activity is normalized by Renilla luciferase activity as the promoter activity (Michelini et al., 2014; Nakajima and Ohmiya, 2010; Roda et al., 2004).

An alternative chemical test using a cell-based assay requires the analysis of a large number of samples. It is therefore preferable to use an improved assay system whereby gene expression can be monitored simultaneously in a one-step reaction in single extracts. Beetle luciferases emit red luminescence during reaction, compared to the green emitted by firefly D-luciferin. The two colors can be divided using an optical filter. The dual color-reporter assay is based on the color difference between beetle and firefly luciferases and is sold commercially as the Tripluc Reporter Assay System by TOYOBO (Nakajima et al., 2004; Nakajima et al., 2005).

In the IL-2 Luc assay, the multicolor luciferase assay system (Nakajima et al. 2005) consisted of a green-emitting luciferase (SLG; lmax = 550 nm) for the gene expression of the IL-2 promoter, an orange-emitting luciferase (SLO; lmax = 580 nm) for the gene expression of the IFN-γ promoter, and a red-emitting luciferase (SLR; lmax = 630 nm) for the gene expression of the internal control promoter, GAPDH.

The three luciferases emit different colors upon reacting with firefly D-luciferin and

their luminescence is measured simultaneously in a one-step reaction by dividing the emission from the assay mixture using an optical filter (Nakajima et al., 2005). First, the total relative light units (F0) are measured in the absence of the filters. Then, the F1 and F2 values that passed through the R56 filter (>560-nm long-pass filters) or the R60 filter (>600-nm long-pass filters), respectively, is measured. The three luciferase activities are calculated using the simultaneous equation shown below by substituting the F0, F1 and F2 values. In this equation, G, O and R are the activities of the green-, orange- and red-emitting luciferases, respectively, κG_{R56}, κO_{R56} and κR_{R56} are the transmission coefficients of the green-, orange- and red-emitting luciferases of the R56 filter, respectively, κG_{R60}, κO_{R60} and κR_{R60} are the transmission coefficients of the green-, orange- and red-emitting luciferases of the R60 filter, respectively.

$$\begin{pmatrix} F0 \\ F1 \\ F2 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \kappa G_{R56} & \kappa O_{R56} & \kappa R_{R56} \\ \kappa G_{R60} & \kappa O_{R60} & \kappa R_{R60} \end{pmatrix} \begin{pmatrix} G \\ O \\ R \end{pmatrix}$$

Luminescence activity is measured using a filtered 96-well microplate luminometer (for example, Phelios (ATTO, Tokyo, Japan), Tristan 941 (Berthold, Bad Wildbad, Germany), and the ARVO series (PerkinElmer, Waltham, MA). It is necessary to calibrate the luminometer in each experiment to ensure reproducibility (Niwa et al., 2010). Recombinant green-, orange- and red-emitting luciferases are available for this calibration.

5. Validation Management Structure

5-1. Validation Management Team (VMT)

Trial Coordinator:	Hajime Kojima (Japanese Center for the Validation of Alternative Methods (JaCVAM), National Institute of Health Sciences (NIHS), Kawasaki, Japan), VMT trial coordinator, Chemical supplier and Management of quality control
Lead laboratory:	Setsuya Aiba (Tohoku University, Miyagi, Japan), Developer of this assay, Test method, expertise underlying science Yutaka Kimura (Tohoku University, Miyagi, Japan)
International expert members	
EU liaison:	Emanuela Corsini (Milan Univ., Italy), Test system expertise, validation expertise, immunotoxicity expertise Erwin L. Roggen (3Rs Management and Consulting ApS, Denmark), Test system expertise, validation expertise, immunotoxicity expertise
ICCVAM liaison:	Dori Germolec (NTP/NIEHS, USA), Immunotoxicity expertise
JSIT liaison:	Tomoaki Inoue (Chugai Pharmaceutical Co., Ltd.), Immunotoxicity expertise
Data management team:	Takashi Omori (Kobe University, Kobe, Japan), Data analysis, biostatistics dossier
Chemical Selection Committee	Setsuya Aiba (Tohoku University) Yutaka Kimura (Tohoku University Hajime Kojima (JaCVAM) Emanuela Corsini (Milan Univ)

	Erwin L. Roggen (3Rs Management and Consulting ApS) Dori Germolec (NTP/NIEHS) Tomoaki Inoue (Chugai Pharmaceutical Co., Ltd.)
Participating Test Facilities	Test Facility 1: Hatano Res. Inst., FDSC, Study Director (SD): Kohji Yamakage Test Facility 2: AIST, Tsukuba, SD: Rie Yasuno Test Facility 3: AIST, Takamatsu, SD: Yoshihiro Nakajima

5-3. Meetings

27-28/1/2016 (Mitoya, Sendai, Japan)
1st International VMT Meeting
Subjects: Kick-off meeting for the MITA assay
VMT members: Corsini, E., Roggen, E., Germolec, D.(telephone), Inoue, T., Kageyama, S., Aiba, S., Kimura, Y., Yamakage, K., Watanabe, M., Kobayashi, M., Yasuno, R., Ohmiya, Y., Omori, T., Kojima, H., Tanabe, S., Venti, S.
Participating laboratories: AIST(Tsukuba), HRI

13/9/2016 (Skype-meeting)
Meeting by Skype
Subjects: Result of the phase 0 study and proposal of the revised protocol

VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T.,
Aiba, S., Kimura, Y., Omori, T., Kojima, H.

4-5/2/2017 (Nayamachi community hall, Kyoto, Japan)
2nd International VMT Meeting
Subjects: Validation results, discussion and suggestion
VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T.,
Aiba, S., Kimura, Y., Yamakage, K., Watanabe, M., Kobayashi, M.,
Yasuno, R., Nakajima, Y., Omori, T., Mori, A., Kobayashi, M.,
Kojima, H., Venti, S.
Participating laboratories: AIST(Tsukuba), HRI, AIST(Takamatsu)

18-19/11/2017 (Umeda Center Building, Osaka, Japan)
3rd International VMT Meeting
Subjects: Validation results, discussion and suggestion
VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T.,
Aiba, S., Kimura, Y., Yamakage, K., Watanabe, M., Kobayashi, M.,
Yasuno, R., Nakajima, Y., Omori, T., Mori, A., Kobayashi, M.,
Kojima, H., Venti, S.
Participating laboratories: AIST(Tsukuba), HRI, AIST(Takamatsu)

29/3/2018 (Skype-meeting)
Meeting by Skype
Subjects: Proposal of the revised protocol
VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T.,
Aiba, S., Kimura, Y., Omori, T., Kojima, H.

10/4/2018 (telephone-meeting)

Meeting by telephone

Subjects: Understanding the unexpected results in the IL-2 Luc assay

VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Kojima, H.

4-6/10/2018 (Kobe Univ., Kobe, Japan)

4th meeting for the MITA Validation study

Subjects: Validation report for the IL-2 assay

VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T. Aiba, S., Kimura, Y., Yamakage, K., Watanabe, M., Yasuno, R., Nakajima, Y., Omori, T., Takagi, Y., Mashimo, N., Kado, Y., Kojima, H., Venti, S.

Participating laboratories: AIST(Tsukuba), HRI, AIST(Takamatsu)

6. Study Design (Appendix 12)

The aim of this phase is to (pre)validate the IL-2 Luc assay method to assess transferability and inter-laboratory variability so that this test can be used to screen for immunotoxic chemicals.

The validation study (Phase I and Phase II trials) was conducted by 3 laboratories, based on the study design and schedule shown in Tables 3 and 4 and using the test chemicals shown in Tables 5 and 6. The methods were described above in section 4: ’Test Method 4.1 IL-2 Luc assay’, and the precise protocol is described below in section 8: ‘Protocol 8.2 Protocol for the IL-2 Luc assay’ in Tables 7-9.

Table 3. The number of chemicals analyzed in the validation study

Studies	Within-Laboratory	Between-laboratories	Predictivity
I	5	5	5
II		20	20
Total	5	25	25

7. Test Chemicals

The selection process for the test chemicals for the IL-2 Luc assay validation study is described below.

In addition, the chemical categories or physical state and chemical properties (e.g., solid, liquid, etc.) are included in the tables of these test chemicals in order to investigate the applicable domain.

Table 4. Breakdown of the IL-2 Luc assay validation study

Phase	The number of the test substances	The number of the repetitions	Examination	Date of experiment start
Pre	5	1	Between- laboratory transferability (Non-coded)	July, 2016
I	5	3	Within- and between- laboratory reproducibility (Coded)	September, 2016
II	20	1	Between- laboratory reproducibility and predictivity (Coded)	May, 2017

7-1. Basic rule for chemical selection

The selection of test chemicals by the Chemical Selection Committee (CSC) in the VMT was based on published papers on *in vivo* immunotoxicity tests and validation studies for *in vitro* alternative assays on immunotoxicity test methods.

7-1-1. The applied selection criteria

- information on mode/site of action
- coverage of a range of relevant chemical classes and product classes
- quality and quantity of reference data (*in vivo* and *in vitro*)
- high-quality data derived from animal and (if available) human studies
- information on interspecies variations (for example: variability with regard to the uptake of chemicals, metabolism, etc.)
- coverage of a range of toxic effects/potencies
- chemicals that do not require metabolic activation
- appropriate negative and positive controls

- physical and chemical properties (feasibility of use in the experimental set-up as implicated by the CAS No.)
- single chemical entities or formulations of known high purity
- availability
- cost

In the first phase of the selection procedure, the CSC identified and collected several existing lists of potential chemical immunotoxicants, such as NTP IMMUNOTOX, EPA candidate list. An extensive literature search was performed by the CSC in order to ensure that all the pre-selected chemicals fulfilled the selection criteria described above. In addition, it was decided that at least 20% of the total chemicals to be tested should provide negative results (i.e., not immunotoxic) in order to increase the statistical power of the data analysis.

7-1-2. Chemical Acquisition, Coding and Distribution

Laboratory transferability, and within- and between-laboratory reproducibility and predictivity, in all test facilities were assessed using coded chemicals. Coding was supervised by JaCVAM, in collaboration with CSC. CSC was responsible for coding and distributing the test chemicals, references, and controls for the validation study.

7-1-3. Handling

The chemical master at each test facility received complete information considered essential regarding the test chemicals (physical state, weight or volume of sample, specific density for liquid test chemicals, and storage instructions) by JaCVAM. Moreover, the test facility chemical master stored each chemical at conditions in accordance with the storage instructions and received sealed safety information such as the Material Safety Data Sheet (MSDS) describing hazards identification and exposure controls/personal protection for each chemical. The test chemicals were delivered directly to the study director and the study director was not shown the MSDSs. The study director was to refer to the MSDSs only in the event of an accident. If the study director referred to the MSDS,

he/she was not to reveal the content of the MSDS to the test facility technicians.

No accidents occurred during the course of the validation study, and all test facilities returned the MSDSs for the test chemicals to JaCVAM in their sealed envelope upon completion of the validation study. All test chemicals were disposed of in compliance with the rules and regulations of the test facilities upon completion of the validation study.

7-2. Pre-validation study

Transferability of this assay was checked using five non-coded chemicals (2-aminoanthracene, citral, chloroquine diphosphate salt, dexamethasone and methylmercury(II) chloride) (Appendix 1) in 4 test facilities, including the lead laboratory. These chemicals were selected by the CSC.

7-3. Validation study -Phase I trial

Within- and between-laboratory reproducibility of this assay was checked using 5 coded chemicals in 3 test facilities. These chemicals were selected by CSC based on the in-house data set of the lead laboratory. The chemicals were coded by JaCVAM as shown in Table 5 (Appendix 2) and distributed to the test facilities.

7-5. Acceptance criteria

The within-laboratory reproducibility for the all test facilities was done by an independent biostatistical analysis using coded five chemicals, under the VMT. The proportion of concordance should be equal or more than 80% as tentative acceptance criteria for phase I study.

Twenty-five coded test items have been selected to confirm the between-laboratory reproducibility in the phase I and II study. At the end of the testing, the test facilities will submit a QC certified copy of whole study dossier to the trial coordinator (study plan in GLP principle, raw data, records and data analysis, study report in GLP principle). The proportion of concordance between-laboratory reproducibility should be equal or more than 80% as acceptance criteria.

8. Protocols

Overview of the IL-2 Luc assay

An overview of the IL-2 Luc assay is shown in Fig. 9. In addition, the final protocol of the present test (version 011.1E) is provided as attached Appendixes 4 and 5, and the procedures are described in detail below.

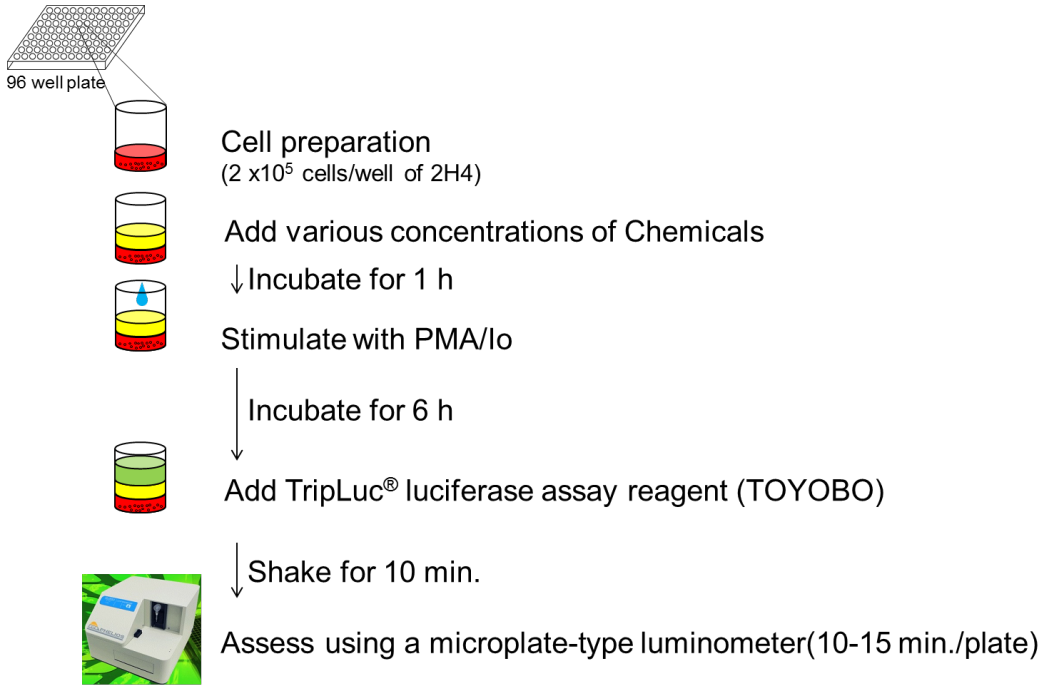

Fig. 9. Overview of the IL-2 Luc assay

8-1 Cells

・/ 2H4 (IL2-SLG、IFNγ-SLO、GAPDH-SLR)

The human acute T lymphoblastic leukemia cell line Jurkat was obtained from the ATCC. A Jurkat-derived IL-2 and IFN-γ reporter cell line, 2H4, that harbors the SLG, SLO and SLR luciferase genes under the control of the IL-2, IFN-γ and GAPDH promoters, respectively, was established by Tsuruga Institute of Biotechnology, TOYOBO Co. Ltd., Fukui, Japan. (Saito et al. 2011)

8-2. Protocol for the IL-2 Luc assay

8-2-1. Reagents and equipment (Appendix 6)

The following reagents and equipment were used.

For maintenance of 2H4 cells

・/ RPMI-1640 (GIBCO Cat#11875-093, 500 mL)

・/ FBS (Biological Industries Cat#04-001-1E Lot: 715004)

・/ Antibiotic-Antimycotic (GIBCO Cat#15240-062)

・/ HygromycinB (CAS:31282-04-9, Invitrogen Cat#10687-010)

・/ G418 (CAS:108321-42-2, Nacalai Tesque Cat#16513-84)

・/ Puromycin (CAS:58-58-2, InvivoGen Cat#ant-pr-1)

For chemical exposure, stimulation and solvents

・/ Ionomycin (CAS:56092-82-1, Sigma Cat#I0634)

・/ Phorbol 12-myristate 13-acetate (PMA) (CAS:16561-29-8, Sigma Cat#P8139)

・/ Ethanol (e.g., Wako Cat#057-00456)

・/ Dimethyl sulfoxide (DMSO) (CAS:67-68-5, Sigma Cat#D5879)

・/ Distilled water (GIBCO Cat#10977-015)

For measurement of luciferase activity

・/ Tripluc® Luciferase assay reagent (TOYOBO Cat#MRA-301)

8-2-2. Culture medium

Various culture media were used depending on the purpose of the cell culture.

Table 7. A medium: for maintenance of 2H4 cells (500 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	440 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	50 mL
Antibiotic-Antimycotic	GIBCO #15240-062	100×	1×	5 mL
Puromycin	InvivoGen #ant-pr-1	10 mg/mL	0.15 μg/mL	7.5 μL
G418	Nacalai Tesque #16513-84	50 mg/mL	300 μg/mL	3 mL
HygromycinB	Invitrogen #10687-010	50 mg/mL	200 μg/mL	2 mL

Table 8. B medium: for luciferase assay (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL

Table 9. C medium: for thawing 2H4 cells (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	26.7 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL
Antibiotic-Antimycotic	GIBCO #15240-062	100×	1×	0.3 mL

8-2-3. Cell line

The Jurkat human acute T lymphoblastic leukemia cell line (ATCC, Manassas, VA, USA), was cultured in RPMI-1640 (Sigma-Aldrich, St. Louis, MO, USA) with Antibiotic-Antimycotic (Invitrogen, Carlsbad, CA, USA) and 10% Hyclone™ fetal calf serum (Thermo Fisher Scientific, Wilmington, NC, USA) (Jurkat growth medium) at 37 °C with 5% CO_2. The luciferase reporter assay system was constructed using three different luciferases, SLG, SLO and SLR, that emit green, orange, and red light, respectively, with a single substrate. In brief, we constructed three luciferase vectors, pSLG-test/Hygr, pSLO-test/Neor, and pSLR-test/Purr, by ligating the BamHI/SacI site of resistant gene vectors containing one of the three resistant genes, hygromycin (SLG), neomycin (SLO) or puromycin (SLR), the SV40 promoter, and HSVtk polyA into the luciferase gene vectors, pSLG-test, pSLO-test and pSLRtest (Toyobo, Osaka, Japan), respectively. The activities of the luciferases can be measured simultaneously and quantitatively using optical filters. This system can rapidly and easily monitor multiple gene expression (Nakajima et al., 2005; Noguchi et al., 2008). Promoter cloning was carried out as follows. The IL-2 promoter construct containing nt －3006 to +286, the

IFN-γ promoter construct containing nt －4971 to +111, and the GAPDH promoter construct containing nt －1373 to +128 from transcription initiation sites that were identified using DBTSS (http://dbtss.hgc.jp/), were amplified from genomic DNA by PCR using KOD-Plus- ver. 2 (Toyobo) for the IL-2 promoter or KOD-Plus- (Toyobo) for the IFN-γ and GAPDH promoters and specific primers. The IL-2 promoter, IFN-γ promoter, or GAPDH promoter was ligated into pSLG-test/Hygr, pSLOtest/Neor or pSLR-test/Purr vectors that had been digested with MluI and XhoI, MluI and SalI, or MluI and EcoRI, respectively. Before transfection, we confirmed the sequence of the 5' and 3' regions of each promoter using a 3730 DNA Analyzer (Applied Biosystems, Foster City, CA, USA). IL-2, IFN-γ and GAPDH reporter plasmids (1 μg) were transfected into Jurkat T cells (5x10^5 cells) using SuperFect (Qiagen, Valencia, CA, USA). After transfection, cells were cultured in Jurkat growth medium containing 200 μg/ml hygromycin (Invitrogen), 300 μg/ml G418 (Nacalai tesque, Kyoto, Japan) and 0.15 μg/ml puromycin (InvivoGen, San Diego, CA, USA) for selection. After repeated limiting dilution, we established a stable cell line (2H4 cells) in Fig.10.

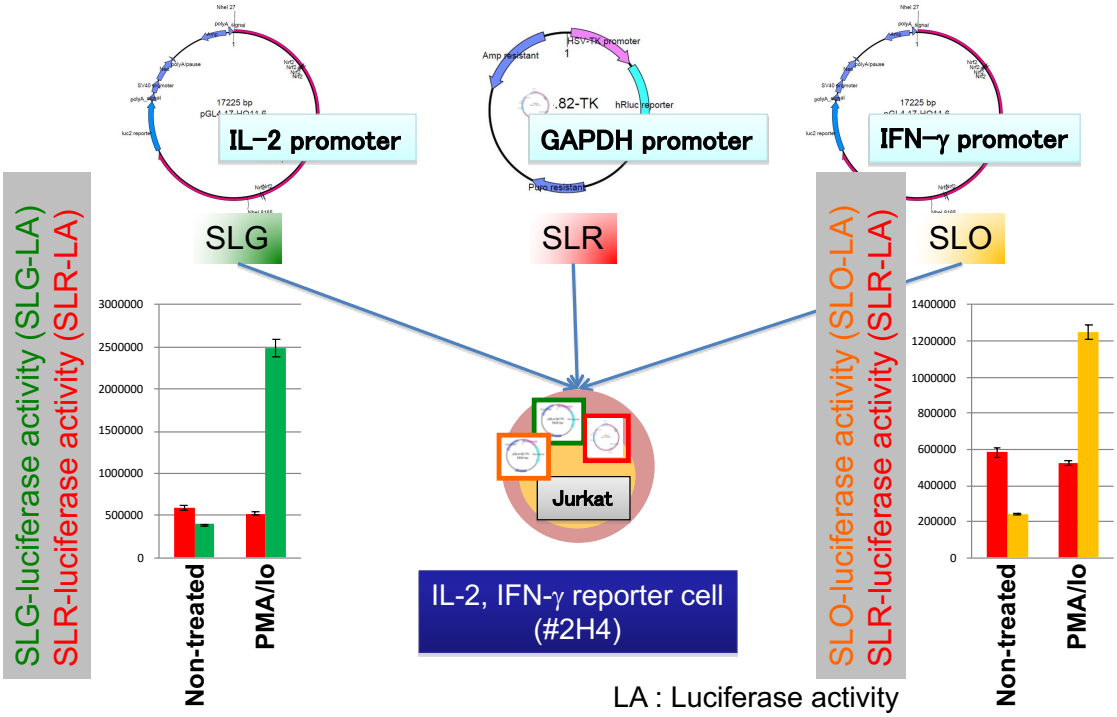

Fig. 10. IL-2 reporter cell, 2H4

8-2-4. Thawing of 2H4 cells

Pre-warm 9 mL of C medium in a 15 mL polypropylene conical tube in a 37°C water bath (for centrifugation) and 15 mL of C medium in a T-75 flask at 37°C in a 5% CO_2 incubator (for culture).

Thaw frozen cells ($2x10^6$ cells/0.5 mL of freezing medium) in a 37°C water bath, then add to a 15 mL polypropylene conical tube containing 9 mL of pre-warmed C medium. Centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in 15 mL of pre-warmed C medium in a T-75 flask. Cells are incubated at 37°C, 5% CO_2.

8-2-5. Maintenance of 2H4 cells

Pre-warm the A medium in a T-75 Flask at 37°C in a 5% CO_2 incubator. The culture medium should be changed to the pre-warmed A medium 3 or 4 days after thawing. At that time, count the number of cells, centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in pre-warmed the A medium in a T-75 Flask. Cells are passaged at $3x10^5$/mL and incubated at 37°C, 5% CO_2.

The interval between subcultures should be 3~4 days. Cells can be used between one and six weeks after thawing.

The lead laboratory has examined how long 2H4 cells could be cultured without losing their reactivity to PMA/Io. 2H4 cells maintained their response to PMA/Io up to 16 weeks or 35 passages.

8-2-6. Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (2.0×10^7 cells for two chemicals are required, but to have

some leeway, 3.0 x 10^7 cells for two chemicals should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 4×10^6/mL. Transfer the cell suspension to a reservoir (Thermo Scientific), and add 50 µL of cell suspension to each well of a 96 well µclear black plate (flat bottom) using an 8 channel or 12 channel pipetman (Gison, Inc, Middleton, WI, USA). (cf. Figure 11)

Fig. 11. Components in each well of 96-well plates after cell preparation.

8-2-7. Preparation of chemicals and cell treatment with chemicals

In Fig. 12, water soluble chemicals were dissolved in distilled water at a concentration of 25 mg/mL. If the chemicals were soluble at 25 mg/mL, then 50 mg/mL solutions were prepared if their solubility was sufficient. If they were not soluble at 50 mg/mL, then 25 mg/mL was judged the highest soluble concentration. If the chemicals were soluble at 50 mg/mL, then 100 mg/mL solutions were prepared if their solubility was sufficient. If they were not soluble at 100 mg/mL, then 50 mg/mL was judged the

highest soluble concentration. If they were soluble at 100 mg/mL, then 100 mg/mL was judged the highest soluble concentration.

Chemicals not soluble in water were dissolved in DMSO at 500 mg/mL. If they were not soluble at 500 mg/mL, the highest soluble concentration was determined by diluting the suspension from 500 mg/mL by a factor of 2 with DMSO. Sonication and vortex mixing were used if needed and the attempt to dissolve the chemical continued for at least 5 minutes. All dissolved chemicals were used within 4 hours of being dissolved in distilled water or DMSO.

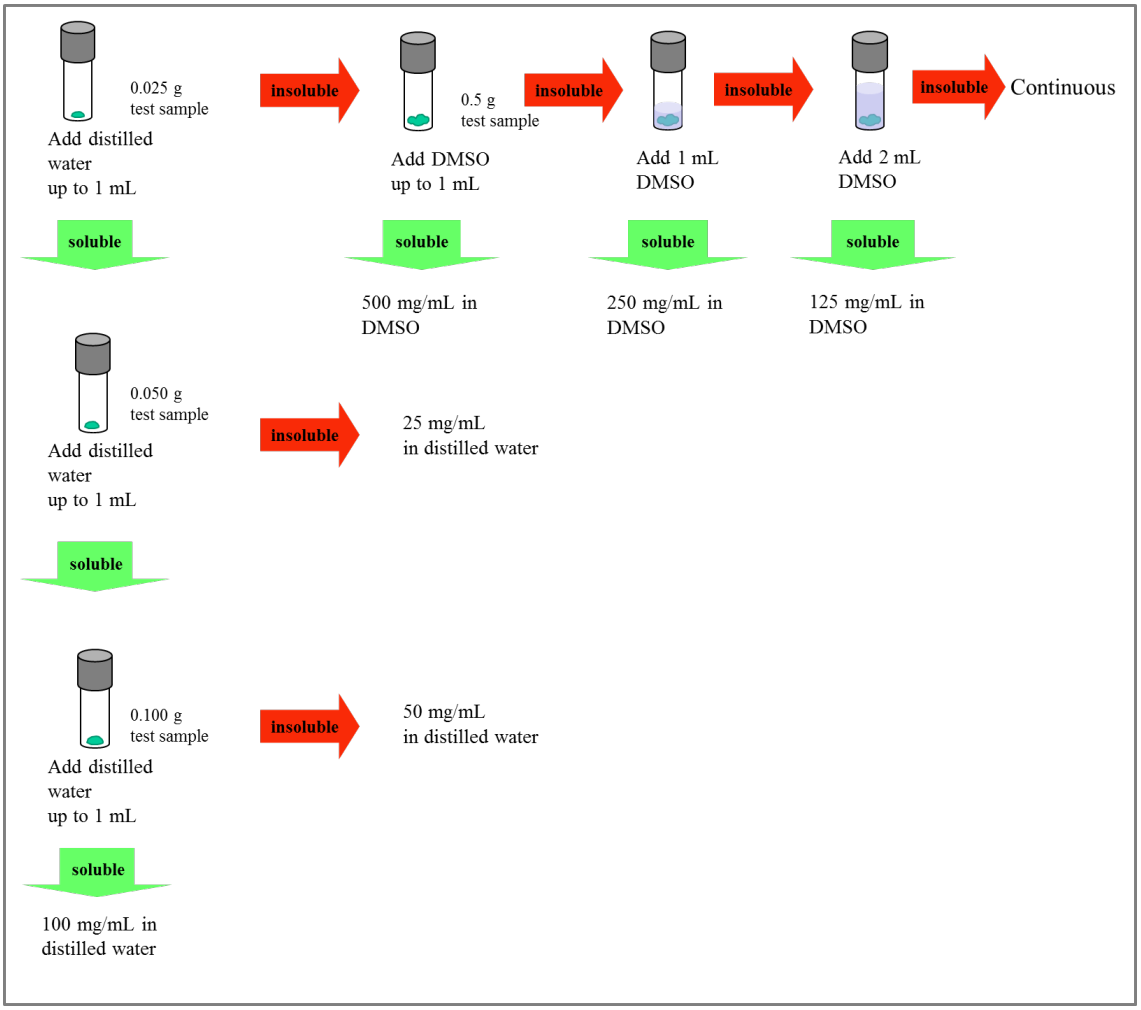

Fig. 12. Dissolution by vehicle

8-2-8. Dilution of chemicals

For water soluble chemicals, 11 serial dilutions were conducted using B medium, diluting by a factor of 2, in the 1st experiment. In the 2nd, 3rd, or 4th experiment, 11 serial dilutions were conducted, diluting by a factor of 1.5. For water insoluble chemicals, 11 serial dilutions were conducted using DMSO as the solvent, diluting by a factor of 2 in the 1st experiment and by a factor of 1.5 in the 2nd, 3rd, and 4th experiments. The diluted chemicals are added to 2H4 cells in a 96 well plate. After one-hour incubation at 37°C in a 5% CO_2 incubator, 2H4 cells are added 10 μL of PMA/Io solution and incubated again at 37°C in a 5% CO_2 incubator for 6 hours.

8-2-9. Measurements

After incubation with the chemical and PMA/Io for 6 h at 37°C in a 5% CO_2 incubator, 100 μL of pre-warmed Tripluc is added to each well in the plate containing reference samples using a pipetman and the plate is shaken for 10 min at room temperature (about 25°C) using a plate shaker. Surface bubbles are removed if present and bioluminescence in each well is measured using a microplate-type luminometer with a multi-color detection system (Phelios; Atto Co., Tokyo, Japan) for 3 sec each in the absence (F0) and presence (F1, F2) of the optical filter. The F0, F1 and F2 data (values are expressed as counts) are processed using an Excel-based data sheet (Appendix 10). SLG-LA, SLO-LA and SLR-LA are calculated for each well based on the algorithm to calculate SLG-LA, SLO-LA and SLR-LA from the raw luminescence data reported previously (Nakajima et al., 2005; Noguchi et al., 2008). In addition to being used to calculate SLG-LA, SLO-LA and SLR-LA, this data sheet can automatically generate final graphs showing the correlation between %suppression and the concentration of chemicals, and between II-SLR-LA and the concentration of the chemical.

8-2-10. Luminometer apparatus

Multi-color detection systems such as microplate-type luminometers are available and include Phelios (ATTO, Tokyo, Japan), Tristan 941 (Berthold, Bad Wildbad, Germany), and the ARVO series (PerkinElmer, Waltham, MA). The luminometer detectors must have high sensitivity and low background noise and are usually equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmission coefficients of these filters for each bio-luminescence signal color must be calibrated prior to all experiments following the manufacturer's recommended protocol because the transmittance of the optical filter or the sensitivity of the detector are dependent on the measurement conditions.

8-2-11. Positive control

In each experimental set, dexamethasone and cyclosporine A are used as positive controls.

8-2-12. Calculation and definition of parameters for the IL-2 Luc assay

In the IL-2 Luc assay, the lead laboratory defined nIL2LA to represent IL-2 promoter activity by the SLG luciferase activity (IL2LA) normalized by SLR luciferase activity (GAPLA). The suppression index of GAPLA (Inh-GAPLA) was obtained by dividing GAPLA of 2H4 treated with chemicals with GAPLA of non-treated 2H4. % suppression reflects the effect of chemicals on IL-2 promoter. (Table 10).

Table 10. Abbreviations used in the 2H4 luciferase assay protocol

Parameter	Definition
IL2LA	Luciferase activity of stable luciferase green (Under the control of IL-2 promoter)
IFNLA	Luciferase activity of stable luciferase orange

	(Under the control of IFN-γ promoter)
GAPLA	Luciferase activity of stable luciferase red (Under the control of GAPDH promoter)
Normalized IL2LA (nIL2LA)	= (IL2LA) / (GAPLA)
Normalized IFNLA (nIFNLA)	= (IFNLA) / (GAPLA)
Inhibition index of GAPLA (Inh-GAPLA)	= (GAPLA of 2H4 treated with chemicals) / (GAPLA of untreated 2H4) (The cytotoxic effect of chemicals)
% suppression	= (1-(nIL2LA of 2H4 treated with chemicals) / (nIL2LA of non-treated 2H4)) x 100 (The effect of chemicals on IL-2 promoter)

8-2-13. Acceptance criteria

The following acceptance criteria should be satisfied when using the IL-2 Luc Assay method.

If Fold induction of nIFNLA of PMA/Io wells without chemicals (=(nIFNLA of 2H4 cells treated with PMA/Ionomycin) / (nIFNLA of non-treated 2H4 cells)) demonstrate less than 3.0, the results obtained from the plate containing the control wells should be rejected.

8-2-14. Prediction model

The experiments are repeated until 2 consistent suppressive (or stimulatory) results or 2 consistent “no effect results” are obtained. When 2 consistent results are obtained, the chemicals are judged as indicated by the obtained consistent results.

An immunotoxicant is identified by the mean of %suppression and its 95%

simultaneous confidence interval.

In each experiment, when the chemicals clearly meet the following 3 criteria, they are judged as suppressive or stimulatory. Otherwise, they are judged as 'no effect' chemicals.

1. The mean of %suppression is ≥35 (suppressive) or ≤-35 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.
2. The result shows 2 or more consecutive statistically significant positive (negative) data points or 1 statistically significant positive (negative) data point with a trend in which at least 3 consecutive data points increase (decrease) in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only 1 data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which I.I.-SLR-LA is ≥0.05.

8-3. Data collection

8-3-1. Operating procedure

The detail of operating procedure in this assay is describe to the protocol version 011E. The version of protocols was updated during the validation studies, but for the operating procedure, the descriptions of operating procedure described in these protocols are same through the 2 validation studies.

8-3-2. Chemicals

For phase I study, in which the main aim was to evaluate intra- and inter-laboratory reliability, a total of 15 coded chemicals, for 3 rounds of 5 chemicals, were distributed to all the 3 laboratories. Because the different code between rounds was used, the technician in each laboratory did not identify the same chemicals. For the phase II study, in which the main aim of phase I was to evaluate inter-laboratory reliability, 20 coded chemicals were distributed.

In this document the codes for the chemicals were re-coded. To indicate the round, the suffix is used such like P101_R1 for the first chemical of the first round in Phase I study:

P1 means Phase I; 01 means the first chemical; _R1 means first round.

The Table 11 shows the chemical coded through this document.

Table 11. The chemical coded through this document

Phase	Chemical code	Lab A	Lab B	Lab C
I	P101_R1, P101_R2, P101_R3, P102_R1, P102_R2, P102_R3, P103_R1, P103_R2, P103_R3, P104_R1, P104_R2, P104_R3, P105_R1, P105_R2, P105_R3	3 rounds	3 rounds	3 rounds
II	P201, P202, P203, P204, P205, P206, P207, P208, P209, P210, P211, P212, P213, P214, P215, P216, P217, P218, P219, P220	1 round	1 round	1 round

8-3-3. Data handling

The developed Excel data sheet for this study was distributed to the laboratories. We had received data files from the 3 laboratories.

From JaCVAM we received files listed the chemical codes for the distributed 5 chemicals for the phase I study, and 20 chemicals for the phase II study.

For the data analysis, these files were combined and some datasets were constructed for the analysis. The SAS ver. 9.4 and Microsoft Excel was used for the data analysis described in this report.

Since the Excel data sheet is able to display a concentration-response plot for %suppression with its 95% confidence interval, we were able to judge “Suppressive”, “Stimulatory” or “Negative” for each experiment by seeing the plot.

8-3-4. Index from each experiment and decision criteria for judgment

The j-th repetition (j = 1 to 4) of the i-th concentration (j = 0 to 11) is measured for IL2LA and GAPLA respectively. The normalized IL2LA is referred as nIL2LA, and is

defined as

$nIL2LA_{ij} = IL2LA_{ij} / GAPLA_{ij.}$

This is the basic unit of measurement in this assay.

8-3-4-1. %suppression

The %suppression is an index for the averaged nIL2LA for the repetition on the i-th concentration compared with it on the 0 concentration, it is the primary measure of this assay. The %suppression is able to write by the following formula,

$$\%\ \text{suppression}_i = \left\{1 - \frac{\left(\frac{1}{4}\right)\sum_i \text{nIL2LA}_{ij}}{\left(\frac{1}{4}\right)\sum_i \text{nIL2LA}_{0j}}\right\} \times 100 \qquad (1)$$

The lead laboratory has proposed that ± 35 of the value suggests suppressive and stimlatory for a tested chemical. This value is based on the investigation of the historical data of the lead laboratory. Data management team followed to use the value through all the phase of present validation study.

The primary outcome measure, % suppression, is basically the ratio of 2 arithmetic means of nIL2LA as shown in equation (1). The 95% confidence interval (95% CI) of the % suppression for the i-th concentration can be estimated.

The lower limit of the 95% CI above 0 is interpreted as that the nIL2LA with the i-th concentration is statistical-significantly greater than it with the 0-concentration, whereas the upper limit of the 95% CI blow 0 is interpreted as that the nIL2LA with the i-th concentration is statistical-significantly lesser than it with the 0-concentration.

There are several ways to construct the 95% CI. We used the method kwon as the Delta method in this study. This 95% confidence interval theorem is obtained from the following formula.

$$\%\text{suppression} \pm 100 \times \left\{z_{0.975} \times \sqrt{\frac{\text{sd}_i^2}{\text{mean}_0^2} + \frac{\text{mean}_i^2 \times \text{sd}_0^2}{\text{mean}_0^4}}\right\},$$

where mean_i is the mean of nIL2LA at the i-th concentration, mean_0 is the mean of

nIL2LA at 0 concentration, sd_i is the standard deviation of nIL2LA at the i-th concentration and sd_0 is the standard deviation of nIL2LA at 0 concentration. $z_{0.975}$ is 97.5 percentile of the standard normal distribution.

8-3-4-2. Inh-GAPLA

The Inh-GAPLA is a ratio of the averaged GAPLA for the repetition of the i-th concentration compared with it of the 0 concentration, and this is written by

$$\text{Inh} - \text{GAPLA}_i = \{(1/4)\text{x}\sum_j \text{GAP LA}_{ij}\}/\{(1/4)\text{x}\sum_j \text{GAP LA}_{0j}\}$$

Since the GAPLA is the denominator of the nIL2LA, the extremely smaller value of this is considered to cause the large variation of the nIL2LA. Therefore, the i-th %suppression value with extremely smaller value of the Inh-GAPLA might be poor precision.

8-3-4-3. Judgment for "Suppressive", "Stimulatory" or "No effect" in each experiment

In each experiment, when the following 3 criteria are satisfied, they are judged as "suppresive" or "stimulatory". Otherwise, they are judged as no effect chemicals.

1. % suppression is ≥ 35 (suppressive) or ≤ -35 (stimulatory) at any dose and statistically significant.
2. The result shows two or more consecutive statistically significant positive (negative) data or one statistically significant positive (negative) data with a trend in which at least 3 consecutive data increase (decrease) in a dose dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained in the concentration at which Inh-GAPLA is ≥ 0.05

For 1, 2, the statistically significant is judged by the lower limit of 95% confidence interval of %suppression is over 0 or the upper limit of it is under 0.

8-3-4-4. Final judgment for “Suppressive” “Stimulatory” or “No effect” using this assay

In this assay, “Suppressive”, “Stimulatory” or “No effect” is defined as in case that the 2 same judgments were found in a set of experiments.

8-3-5. Reliability

8-3-5-1. Within-laboratory reproducibility for 5 common chemicals

Within-laboratory reproducibility was determined by whether or not tables of 3 sets for the final judgment for each chemical by each laboratory were concordant. The concordance rate was then calculated as a proportion of the concordance of each laboratory.

The concordance rate for within-laboratory reproducibility was based on the results of 3 sets.

To summarize, the concordance rate for within-laboratory reproducibility from the 3 laboratories were used to calculate the averaged concordance rate.

8-3-5-2 Between-laboratory reproducibility

Between-laboratory reproducibility was determined using the results from the final judgment from the 3 laboratories for 25 chemicals, this is, 5 chemicals in Phase I study and 20 chemicals in Phase II study. These judgements were tabulated, then the concordance rate was calculated as a proportion of the concordance in each laboratory.

To summarize, the concordance rate for between-laboratory reproducibility from the 3 laboratories were used to calculate the averaged concordance rate.

.

8-3-6. Predictivity

In the evaluation of predictivity, we did not distinguish suppression and stimulation, because both of these indicate modulation of immune function. Then, we dealt as “Positive (P)” in case of “suppression” or “stimulation”, and “No effect (N)” in case of

no significant effects for each chemical judgement.

The concordance, sensitivity and specificity were estimated as the indexes of predictivity. These indexes were estimated using the frequency results obtained from the 2 by 2 contingency table for T cell targeting. The definitions of these indexes are summarized in Table 12 below. This calculation was based on the results decided by a majority for the between-laboratory results for each chemical.

Table 12. Definition of the concordance, sensitivity and specificity

Judgment from the IL-2 Luc assay	Chemical category		Total
	Positive	Negative	
Positive	a	b	a+b
Negative	c	d	c+d
Total	a+c	b+d	N

Sensitivity = 100 × a / (a+c)

Specificity = 100 × d / (b+d)

Accuracy = 100 × (a+d) / N

8-4. Quality assurance

Assays and quality assurance were carried out in the spirit of GLP, although not all the participating laboratories routinely worked under GLP certification. The participating laboratories conducted the experiments in accordance with the protocol provided by the VMT. All raw data and data analysis sheets were pre-checked for quality by each laboratory and then were reviewed by the VMT quality assurance team. The results accurately reflect the raw data.

9. Results

We conducted Phase I and II studies in this validation. The assay procedure and criteria used to judge immunotoxicants in the validation studies are summarized in Fig. 13.

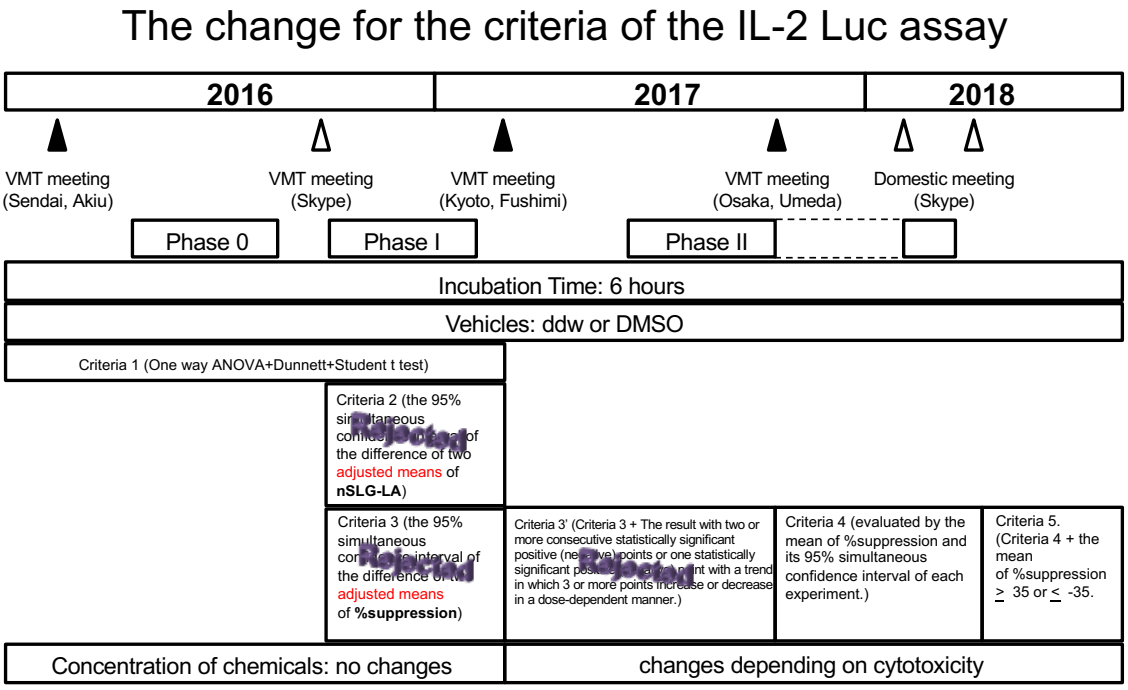

Fig. 13. The modification of the protocols of the IL-2 Luc assay.

9-1. The final criteria

9-1-1. Acceptance criteria

The following acceptance criteria should be satisfied when using the MITA method. In each time of the experiments, a control experiment examining nIL2LA of 2H4 cells treated with PMA/Io and nIL2LA of non-treated 2H4 cells must be conducted. Then, the fold induction of nIL2LA of PMA/Ionomycin wells without chemicals (= (nIL2LA of 2H4 cells treated with PMA/Ionomycin)/(nIL2LA of non-treated 2H4 cells)) is calculated. If the fold induction is less than 3.0, the results obtained from these experiments should be rejected.

9-1-2. Prediction model

The experiments are repeated until 2 consistent suppressive (or stimulatory) results or 2 consistent “no effect results” are obtained. When 2 consistent results are obtained, the chemicals are judged as indicated by the obtained consistent results.

An immunotoxicant is identified by the %suppression and its 95% simultaneous confidence interval.

In each experiment, when the chemicals clearly meet the following 3 criteria, they are judged as suppressive or stimulatory. Otherwise, they are judged as ‘no effect’ chemicals.

1. The mean of % suppression is ≥35 (suppressive) or ≤-35 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.
2. The result shows 2 or more consecutive statistically significant positive (negative) data points or 1 statistically significant positive (negative) data point with a trend in which at least 3 consecutive data points increase (decrease) in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only 1 data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is ≥0.05.

9-1-3. Predictivity

To determine the performance of the IL-2 Luc assay, it is crucial to understand the immunotoxicological characteristics of the chemicals used in the study. Since the IL-2 Luc assay focuses on the effects of chemicals on IL-2 transcription by T cells, we attempted to classify the chemicals into two categories: (i) immunotoxic chemicals which target T cells (TTCs), which include chemicals that directly affect T cell viability, T cell proliferation or T cell function and (ii) others (NTTCs), which include chemicals that do not directly affect T cell viability, T cell proliferation or T cell function. In this assay, to define TTCs, we first surveyed the literature and collected the following six findings regarding each of the chemicals proposed for use in the study in Table 13.

Table 13. The immunotoxicological data obtained from the literature.

Endopoints	Information
Endpoint 1	Decreased thymus weight
Endpoint 2	Increased or decreased IL-2, IFN-γ, IL-4 or other T cell-specific cytokine mRNA expression or protein production by T cells in *ex vivo.*
Endpoint 3	Increased or decreased IL-2, IFN-γ, IL-4 or other T cell-specific cytokine mRNA expression or protein production by T cells *in vitro.*
Endpoint 4	Suppressed T cell proliferation
Endpoint 5	Suppressed cytotoxic T cell response
Endpoint 6	The NTP data clearly indicate that one of the immunotoxic mechanism of chemicals are attributed to its effect on T cells.

Then, according to the rationale for classifying immunotoxic chemicals reported by Luster et al (Luster et al., 1992b), we defined TTCs as chemicals that satisfy one of the following criteria and then, made the reference data on immunotoxicity of chemicals in Table 14.

Table 14. The criteria to classify immunotoxic chemicals by affecting T cells.

Criteria	Definition
Criterion 1	Decreased thymus weight with additional one or more findings among endpoints 2 to 5
Criterion 2	Increased or decreased mRNA expression or protein production in one or more cytokines in Endpoints 2 or 3 in multiple reports
Criterion 3	Increased or decreased mRNA expression or protein production in two or more cytokines in Endpoints 2 or 3
Criterion 4	The presence of data suggesting that one of the immunotoxic mechanisms of the chemical was attributed to an effect on T cells in Endpoint 6

Then, by comparing the results of the IL-2 Luc assay (positive or no effect) with the classification of the chemicals (TTC or NTTC), we calculated the accuracy, sensitivity and specificity of the IL-2 Luc assay in the validation study.

To classify 25 chemicals used in the Phase I and II studies, we used the chemical information kindly provided by the National Toxicology Program (NTP). The immunotoxic characteristics of each chemical are shown in Appendix 7. The summarized data of the NTP data and the data collected by the VMT member are shown in Appendix 19. The list of references is in Appendix 8. As already described, IL-2 exerts pleiotropic actions on CD4+ T cell differentiation via its modulation of cytokine receptor expression. Indeed, IL-2 promotes Th1 and Th2 differentiation, while it also drives Treg differentiation. Therefore, it suggests that the augmentation of IL-2

transcription can lead to either immunostimulation or immunosuppression depending on surrounding tissue environment *in vivo.* Therefore, in this assay, if chemicals were judged as either stimulation or suppression, they were both considered as positive (P) and if not, they were judged as negative (N).

9-2. Phase 0 study (for technical transfer)

The preliminary test trial (Phase 0) was performed by the participating laboratories following explicit explanations of the Multi-ImmunoTox Assay protocol Ver. 008.1E by the lead laboratory, Tohoku University. Three laboratories participated in the Phase 0 study of the IL-2 Luc assay using 5 open labeled chemicals, 2-aminoantracene, citral, chloroquine, dexamethasone, methyl mercuric chloride and conducted 1 set (3 experiments) for each chemical. Most response patterns for the 5 chemicals were similar among the 3 laboratories except for 2 early experiments conducted by the naïve laboratory. Based on these results, VMT judged that technical and protocol transfer of the IL-2 Luc assay is acceptable.

After the Phase 0 study, we amended the protocol as follows:

- We changed the speed of centrifugation of the cells, and the preparation method for the selection antibiotics and PMA/Io.
- We set nIFNLA >3 as an acceptance criterion.
- Because nIL2LA is dependent on the properties of the specific luminometer used, we expressed the results of the data by %suppression, which is determined by dividing nIL2LA of the chemically treated cells by nIL2LA of the vehicle-treated cells.
- Volatile chemicals were to be sealed.
- We determined the criteria to judge chemicals from a statistical standpoint (Criteria 2).

9-3. Phase I study (for within and between-laboratory reproducibility)

9-3-1. Test conditions

A total of 5 coded chemicals (4 T cell targeting and 1 non-T cell targeting) were evaluated by 3 experimental sets in the Phase I study based on the Multi-ImmunoTox Assay protocol Ver. 011E.

In each experimental set, 3 or more experiments were conducted for each chemical.

Chemicals that satisfied criteria 5 were judged as positive. Chemicals that provided 2 positive results were judged as immunotoxicants in Tables 15 and 16.

9-3-2. Within-laboratory variation assessments in the Phase I study

Lab A	80.0% (4/5)
Lab B	100% (5/5)
Lab C	80.0% (4/5)
Average	86.7% (13/15)

9-3-3. Between-laboratory variation assessments in the Phase I study

Between-Lab reproducibility (Based on Majority)

80.0% (4/5)

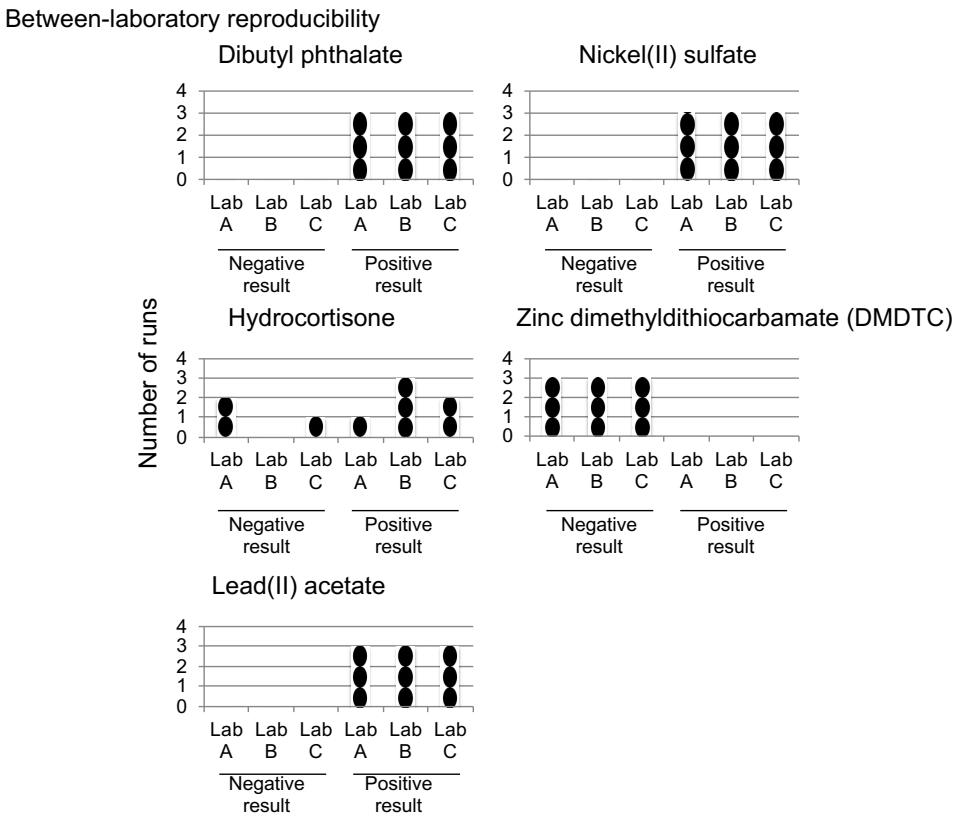

Fig. 14. Between- and within- laboratory variation assessments in the Phase I study

The Phase I study examined within-and between-laboratory reproducibilities using a total of 5 coded chemicals (4 T cell targeting and 1 non-T cell targeting) evaluated by 3 experimental sets based on the MITA protocol Ver. 008.5E. Closed circles represent the judgments for individual experiments for within-laboratory reproducibility or the judgments in individual experimental sets for between-laboratory reproducibility.

9-4. Phase II study (for between-laboratory reproducibility and predictivity)

9-4-1. Test conditions

The Phase II study for between-laboratory reproducibility and predictivity was conducted using a total of 20 coded chemicals (12 T cell targeting, 7 non-T cell targeting and 1 undetermined) and evaluated by 1 experiment set based on the Multi-ImmunoTox Assay protocol Ver. 011E in Tables 17 to 19.

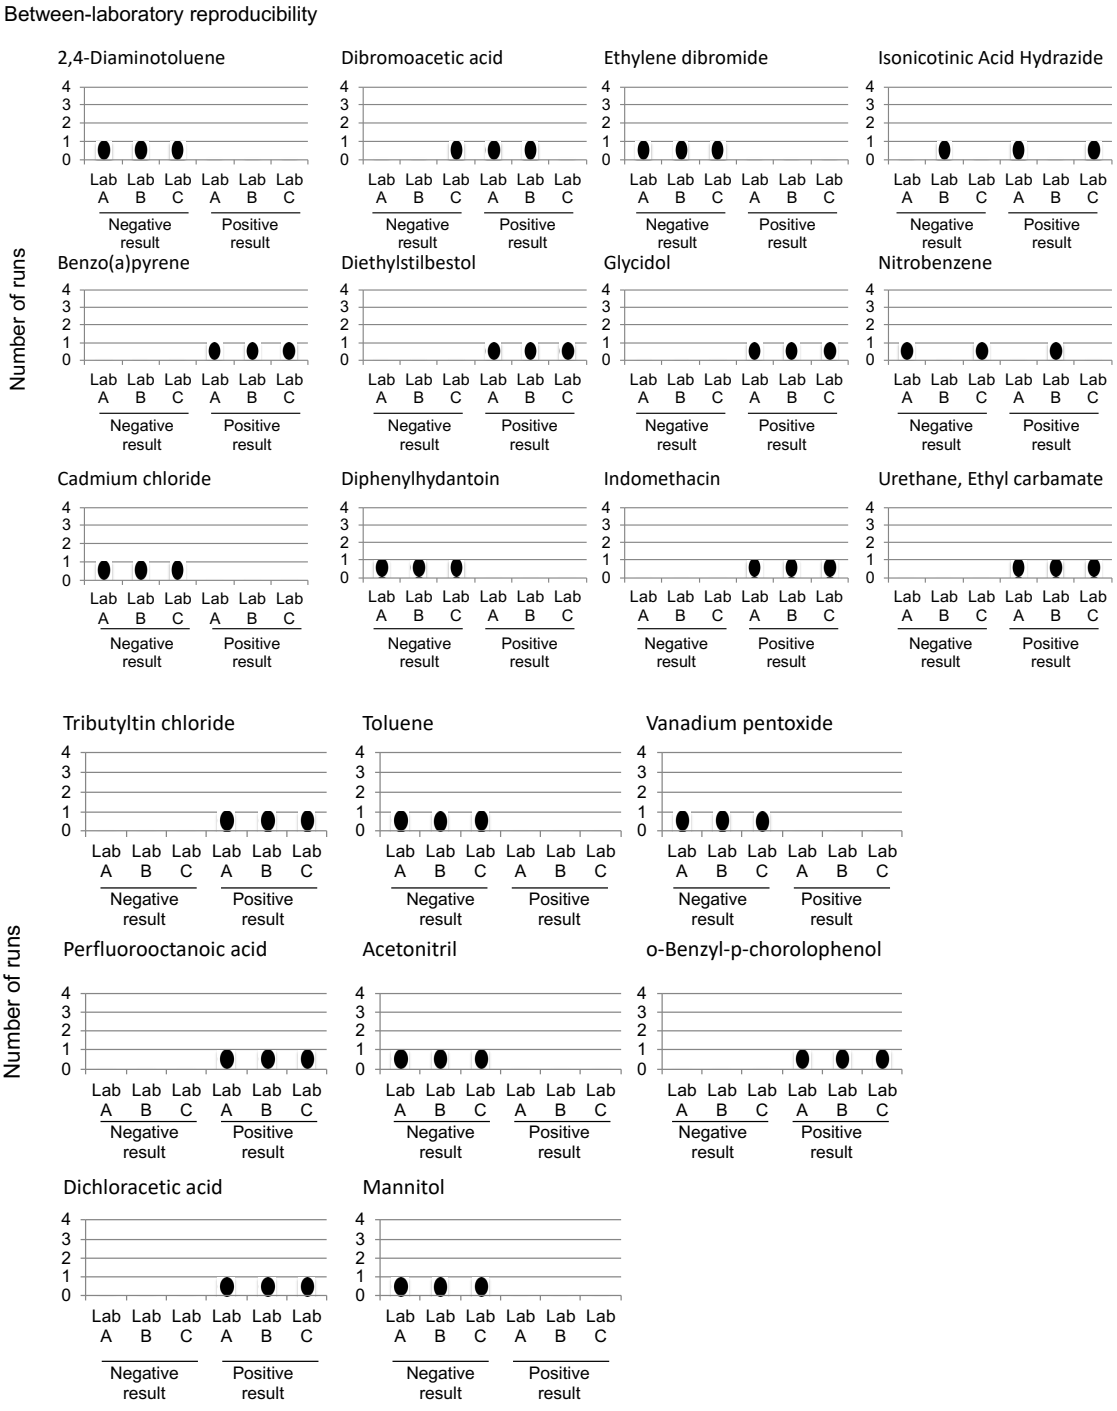

Fig. 15. Between variation assessments in the Phase II study

The Phase II study examined between-laboratory reproducibility using a total of 20 coded chemicals (13 T cell targeting, 6 non-T cell targeting and 1 undetermined) evaluated by 1 experiment sets based on Multi-ImmunoTox Assay protocol Ver. 011E. Closed circles represent the judgments for individual experiments in within-laboratory reproducibility or represent the judgments in individual experimental sets for between-laboratory reproducibility.

9-5. Quality assurance

9-5-1. Chemical Acquisition, Coding and Distribution

The assessment of laboratory transferability, and within- and between-laboratory reproducibility and predictivity, in all test facilities were performed with the coded chemicals. The coding was supervised by JaCVAM (Appendix 14). JaCVAM was responsible for coding and distributing the test chemicals for the validation study.

9-5-2. Handling

The chemical master at each test facility received complete information considered essential regarding the test chemicals (physical state, weight or volume of sample, specific density for liquid test chemicals, and storage instructions) by JaCVAM. Moreover, the test facility chemical master stored each chemical at conditions in accordance with the storage instructions and received sealed safety information such as the Material Safety Data Sheet (MSDS) describing the hazards identification and exposure controls/personal protection for each chemical. The test chemicals were delivered directly to the study director and the study director was not shown the MSDSs. The study director was to refer to the MSDSs only in the event of an accident. If the study director referred to the MSDS, he/she was not to reveal the content of the MSDS to the test facility technicians.

No accidents occurred during the course of the validation study, and all test facilities returned the MSDSs for the test chemicals to JaCVAM in their sealed envelope upon completion of the validation study. All test chemicals were disposed of in compliance with the rules and regulations of the test facilities upon completion of the validation study.

9-5-3. Independent analysis by the biostatistician

All data sheets from the participating laboratories were collected and checked by Dr. Takashi Omori, Kobe univ., the independent biostatistician and JaCVAM. Dr. Omori and his colleagues summarized the data (Appendix 11) and the concentration-response plot for each experiment in phase I (Appendix 17) and phase II (Appendix 18).

9-5-4. Quality assurance by JaCVM

All the record sheets from the participating laboratories were also checked and JaCVAM (Appendix 13). The record sheets mean “Reagent records, solubility test, Cell culture records, Test records and data sheets”. They are total more than 300 pages and available at JaCVAM website (http:// http://jacvam-jp.check-xserver.jp/validation08-login.html). Testings performed as part of a validation study were carried out in accordance with the principles of GLP (OECD, 1998) and necessarily include, without being limited to, the use of protocol and adequate recording of data as well as suitable reporting of results and archival record keeping.

The culture of the cells, the preparation and application of test chemicals and data sheets were completed and the results accurately reflect the raw data. Unfortunately, the record sheets on the maintenance of measuring instruments had not collected before the validation study. JaCVAM considered these records had concerns on quality of data in the validation study. However, JaCVAM checked carefully all the results and judged all data within acceptable ranges.

At least, the reliability of measuring instruments would be checked by an independent organization before the validation study. JaCVAM recommend the validation management team the formal validation study participated with GLP laboratories will be done.

9-6. Combined results of the Phase I and II studies (for between- and within-laboratory reproducibility and predictive capacity)

10. Discussion

10-1. Reliability

The IL-2 Luc assay is based on the modulation of PMA + ionomycin-induced luciferase activity in the IL-2 reporter cell line, 2H4. Therefore, it is crucial that 2H4 cells maintain their ability to induce luciferase activity following stimulation by PMA/Io. Before and during this validation study, the response of 2H4 cells to PMA/Io was carefully observed. We confirmed that a frozen stock of 2H4 cells can be cultured without losing luciferase activity for at least 16 weeks or 35 passages.

The culture of 2H4 cells is relatively simple and does not require the use of trypsin or EDTA because 2H4 cells do not adhere to the culture dishes. First, cells adjusted to the optimum concentration are seeded into each well of a 96-well culture plate. Then, chemicals at graded concentrations are added to the wells. After 6 h incubation, 100 μL of pre-warmed Tripluc is added to each of the 96 wells. The subsequent process is completely automated, except for calculating the results using the predesigned Excel spreadsheet. Therefore, the IL-2 Luc assay is a test method that can significantly reduce human error.

Moreover, the IL-2 Luc assay does not require the determination of cell viability after chemical treatment. 2H4 cells can present IL-2 promoter activity as well as promoter activity of GAPDH, a well-known housekeeping gene; therefore, information regarding the effects of the chemical on both IL-2 induction and cell viability is obtained in each experiment. Furthermore, a single experiment takes only 8 h, including the time required for chemical preparation and cell plating, making the IL-2 Luc assay a true high-throughput method.

10-2. Between- and within-laboratory reproducibility

We examined within-laboratory reproducibility in the Phase I study. Lab A, Lab B, and Lab C demonstrated 80%, 100%, and 80% reproducibility, respectively. On the other

hand, the between-laboratory reproducibility of Lab A, Lab B, and Lab C demonstrated 80% in the combined data of the Phase I and Phase II studies. These results satisfied the acceptance criteria for the validation study with a within-laboratory reproducibility of at least 80% and a between-laboratory reproducibility of at least 80%.

10-3. Predictivity

10-3-1. Rationale to determine the predictivity of the IL-2 Luc assay by the concordance between positive effects and the immunotoxic effects targeting T cell response

Reference data showing which chemicals are immunotoxic are essential for determining the performance of the IL-2 Luc assay. However, such reference data are lacking for most chemicals and thus we attempted to create reference data for the chemicals used in this study. Although there is no gold standard to date for classifying immunotoxic chemicals, Luster et al. (Luster et al., 1992b) proposed a rationale for immunotoxic classification, when they presented a screening battery using a 'tier' approach for detecting potential immunotoxic compounds in mice (Luster, 1998). Their proposal was that a positive reference chemical would either produce a significant dose-response effect in the immune test or significantly alter two or more immune test results at the highest dose of the chemical tested. They classified chemicals based on the 1results obtained in 12 immune tests according to this rationale and found a significant correlation between the judgment of immunotoxic chemicals and host resistance (Luster et al., 1993). Therefore, we used this rationale and classified chemicals based on the published previously immunotoxicological information for each chemical.

When immunotoxic information of chemical is collected from the literature, however, most of the published data are not focusing on whether immunotoxicity of chemicals is caused either by their direct effects on T cell or not. To overcome this problem, in this study, the predictivity was evaluated by the criteria whether chemicals affect T cell functions, namely T cell targeting, or not. To determine T cell targeting chemicals (TTCs), we defined the criteria described in 9-1-3.

10-3-2. The predictivity of the Phase I and Phase II studies

To classify 25 chemicals used in the Phase I and II studies, we used the chemical information kindly provided by the National Toxicology Program (NTP) and those collected by the VMT members. The immunotoxic characteristics of each chemical are shown in Appendix 7 and their summarized data are shown in the Appendix 19. Based on the criteria, the 25 chemicals were classified into 16 TTCs, 8NTTCs, and 1 unclassified chemicals that could not be classified because of insufficient data. According to this classification, the sensitivities of the assays as conducted by Lab A, Lab B, Lab C, and their average in the combined data of the Phase I and II studies are 75.0%, 75.0%, 75.0% and 75.0%, respectively. The specificities of the assays as conducted by Lab A, Lab B, Lab C, and their average are 75.0%, 75.0%, 75.0%, and 75.0%, respectively. The accuracies of the assays conducted by Lab A, Lab B, Lab C, and their average are 75.0%, 75.0%, 75.0%, and 75.0%, respectively.

10-4. IL-2 Luc assay data set for 60 chemicals

Based on the Multi-ImmunoTox assay protocol Ver. 011E and the Criteria 5, the lead laboratory reevaluated the data of 60 chemicals reported previously (Kimura et al. 2018) (Table 23). These 60 chemicals were also classified by the criteria described in 9-1-3. The classification of chemicals and their immunotoxic information were summarized in the Appendix 20. The list of references is in the Appendix 9. There were 34 TTCs, 6 NTTCs, and 20 chemicals that were either those without any immunotoxic information or with insufficient information. Similar to the classification by the criteria used in our published paper (Kimura et al., 2018), TAC, CyA, and Dex significantly suppressed IL-2 luciferase activity (IL-2LA), although the average LOEL of TAC and CyA was significantly lower that of DEX. The off-label immunosuppressive drugs, chloroquine, minocycline, and dapsone significantly suppressed IL-2LA. Anti-cancer drugs, actinomycin D and cisplatin also significantly suppressed IL-2LA. In addition,

azathioprine and colchicine were demonstrated to suppress IL-2LA by the Criteria 5. Again, the suppressive effects on the IL-2LA was not demonstrated by some of immunosuppressants the mechanism of which is inhibition of DNA synthesis or anti-proliferative effects on T cells, such as mitomycin C, cyclophosphamide, methotrexate or mizoribine by the Criteria 5.

If we calculated the predictivity of 60 chemicals evaluated by the IL-2 Luc assay based on the classification of chemicals defined in 9-1-3, the sensitivity, specificity and accuracy (predictivity) are 82.4% (28/34), 83.3% (5/6), and 82.5% (33/40), respectively.

*: cyclophosphamide needs metabolic activity to demonstrate the activity

10-5. Factors responsible for false negative results in the IL-2 Luc assay

Although the within- and between-laboratory reproducibility satisfied the acceptance criteria for the validation study, the predictivity was less than 80%. We considered at least 2 reasons for the poor predictivity of the assay.

1)/ We collected immunotoxic information on the chemicals as much as possible and determined whether the chemicals exhibited T-cell dependent immunotoxicity or not using the criteria we proposed. The information used for classification were the effects of the chemicals on thymus weight, the production of cytokines predominantly produced by T cells, *in vitro* or *ex vivo*, T cell proliferation, and their reported mode of action on T cell function. However, the information available was very limited for most chemicals and very little data had been reproduced by different laboratories. The classification of some chemicals may not be correct.

2)/ The IL-2 Luc assay does not cover every aspect of the effects of the chemicals on T cell function. Other assays targeting T cell functions may be mandatory.

10-6. The applicability domain and the imitations of the IL-2 Luc assay

The IL-2 Luc assay evaluates the effects of chemicals on IL-2 transcription by T cells. Therefore, its applicability domain is immunotoxic chemicals the toxicity of which is caused by the direct effects of chemicals on T cells.

On the other hand, since the 2H4 cell line used in the IL-2 Luc assay is derived from Jurkat cells, a human acute T lymphoblastic leukemia cell line, it is conceivable that this cell line is more resistant to the cytotoxic effects of chemicals than bone marrow cells.

Therefore, the IL-2 Luc assay cannot evaluate the immunotoxic effects of some immunosuppressive drugs the mechanism of which is inhibiting DNA synthesis leading to myelotoxicity (Kimura et al., 2014). Thus, these chemicals in addition to chemicals that need metabolic activation should be outside the applicability domain. To overcome this drawback at present, the IL-2 Luc assay must be combined with assays capable of detecting myelotoxicity, such as *in vitro* myelotoxicity tests (Pessina et al., 2003). Similar to other *in vitro* test methods, poor water soluble chemicals are not suitable for this assay.

10-7. Potential of the IL-2 Luc assay

The IL-2 Luc assay evaluates the effects of chemicals on IL-2 transcription by Jurkat T cells stimulated with PMA and CI. The simultaneous stimulation of PMA and calcium ionophore or ionomycin surrogates the stimulation by T cell receptor (TCR) and CD28 (Kumagai et al., 1987; Truneh et al., 1985). The downstream signaling after the stimulation by TCR/CD28 is shown in Fig. 16. It indicates that the signaling required for IL-2 transcription after TCR/CD28 or PMA/CI stimulation involves the pathways leading the activation of AP1/2, mTOR, NF-κB, and NFAT. The immune system is composed of innate immune system and acquired immune system at least. The innate immune systems are activated by pathogen-associated molecular patterns (PAMPs) or damage-associated molecular patters via Toll-like receptors (TLRs), RIG-I-like receptors (RLRs), Nod-like receptors (NLRs), or cytokine receptors for IL-1 family or TNF family. Most of the downstream signaling after the stimulation of these receptors involves NF-κB and AP1/2 pathways (Newton and Dixit, 2012). In the acquired immune system, in addition to the process of T cell activation, B cell activation after B cell receptor stimulation and the signaling of various cytokines also involves NF-κB pathway (reviewed by Zhang and Sun (Zhang and Sun, 2015). Therefore, it is conceivable that the effects of chemicals on quite a few aspects of immune responses can be detected by the IL-2 Luc assay.

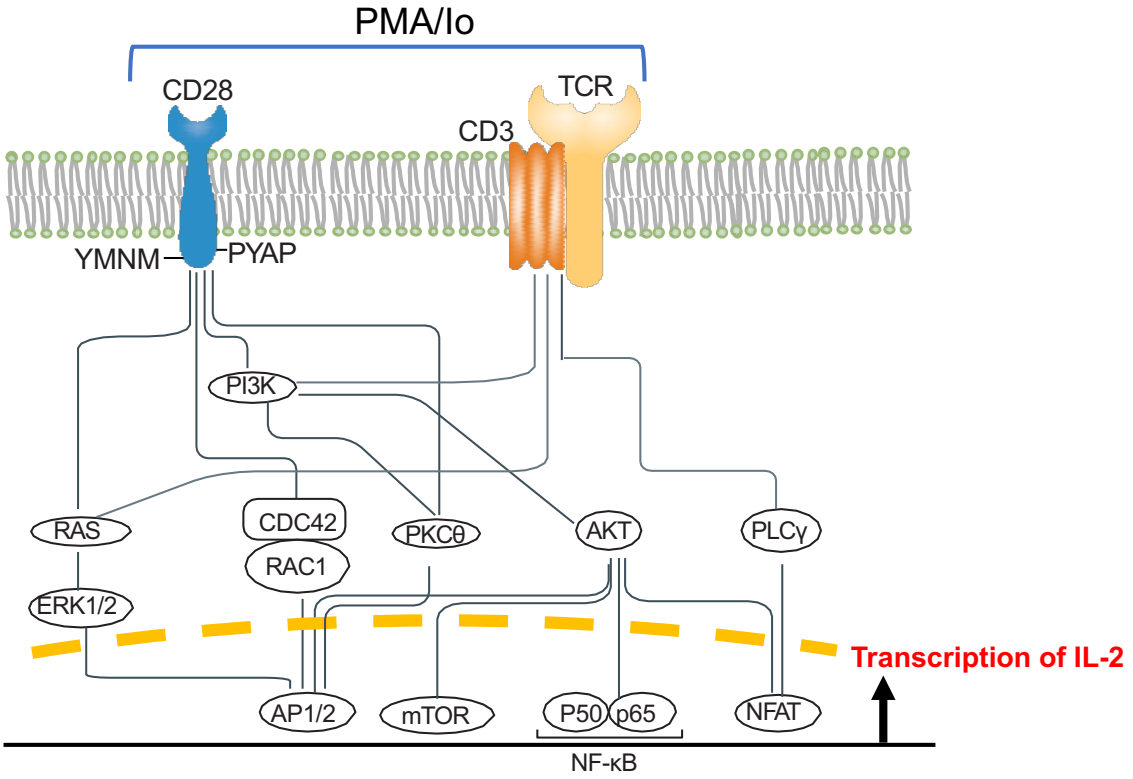

Fig. 16. The schematic presentation of cellular signaling after TCR/CD28 or PMA/Io stimulation.

Luster et al (Luster, 1988) proposed a screening battery using a 'tier' approach for detecting potential immunotoxic compounds in mice. Then, they defined criteria to classify immunotoxic chemicals using several parameters comprising the ‘tier approach’ and then, classified 51 chemicals into immunotoxic compounds or not (Luster et al., 1992b). Furthermore, they examined the ability of various immune tests to predict increased susceptibility in the host resistance classification (Luster et al., 1992a). Their final results demonstrated the following. 1. a number of the immune tests provided a relatively high association with changes in host resistance (i.e. > 70%) such as IgM plaque forming cell (PFC) response to sheep red blood cells, T cell mitogen response,

delayed hypersensitivity response (DHR), surface markers and spleen cellularity while several of the tests, such as leukocyte counts and lymphoproliferative response to LPS, were poor predictors with concordance values of approximately 50%. 2. The combinations of two immune tests compared with the host resistance classification increased the concordance from that obtained using individual tests. Pair-wise combinations which included either the PFC response, surface markers or DHRs gave consistently higher concordances.

When the IL-2 Luc assay examined 31 of the 51 chemicals evaluated by Luster et al. (1992b), its performance was similar to that of mixed lymphocyte reaction (MLR), DHR, and spleen cellularity and better than leukocyte counts or LPS response. Moreover, among 7 chemicals judged as false negative by the IL-2 Luc assay, 5 chemicals was judged as positive by Luster et al. (1992b) based on their suppressive effects on T cell mitogen response. Since our previous study demonstrated the inability of the IL-2 Luc assay to detect immunosuppressive effects of chemicals which are dependent on their suppressive effects on T cell proliferation, these 5 chemicals are out of applicability domain. Taking this into account, the sensitivity, specificity and accuracy of the IL-2 Luc assay was 76.5% (13/17), 44.4% (4/9), and 65.4% (17/26).

The HWBCRA, previously used in a rigorous prevalidation effort by ECVAM and other groups, is an immune test to examine the effects of chemicals on IL-4 or IL-1β production stimulated by staphylococcal enterotoxin B (SEB) or LPS, respectively (Langezaal et al., 2002). Although this study uses human whole blood cells, it examines the production of IL-4 by T cells and of IL-1 by monocytes. This concept is similar to that of the MITA, in which the effects of chemicals on T cells and monocytes are examined using Jurkat cell-derived 2H4 and THP-1-derived THP-G1b cells. Interestingly, the evaluation of chemicals by IL-4 production in the HWBCRA was almost identical to the results of the IL-2 Luc assay: both detected strong immunosuppression by FK506, cyclosporin A, dexamethasone and actinomycin D, which are more potent that chloroquine and azathioprine. Cyclophosphamide and

mizoribine require metabolic activation and thus are not considered as immunosuppressive by both assays. On the other hand, the cardiac glycoside digoxin is classified as an immunotoxic chemical by both assays. These data suggest that the IL-2 Luc assay may be an alternative method to the HWBCRA for examining the effects of chemicals on T cells. In addition, the IL-2 Luc assay has the following advantages over the HWBCRA. 1) The IL-2 Luc assay does not require primary cells, 2) it does not require cytokine quantification using ELISA, and 3) the time required for the IL-2 Luc assay is less than 8 h.

Finally, The performance of the IL-2 Luc assay to examine only immunosuppressive drugs whose effects on human are well established (reviewed by Allison (Allison, 2000)) showed that tacrolimus (TAC), cyclosporine A (CyA) and dexamethasone (Dex) significantly suppressed IL-2 luciferase activity (IL-2LA), although the average Lowest Observed Effect Levels (LOELs) of TAC and CyA were significantly lower that of DEX. The off-label immunosuppressive drugs chloroquine, minocycline and dapsone significantly suppressed IL-2LA. The anti-cancer drugs actinomycin D and cisplatin also significantly suppressed IL-2LA. In addition, azathioprine and colchicine were demonstrated to suppress IL-2LA. No suppressive effects on IL-2LA were demonstrated by several immunosuppressants which inhibit DNA synthesis or anti-proliferative effects on T cells, such as rapamycin, mizoribine, cyclophosphamide, methotrexate and mycophenolic acid.

10-8. Evaluation of the immunotoxicity of 60 chemicals by the modified MITA (mMITA)

Regulatory authorities worldwide require testing for allergic contact dermatitis (ACD) and appropriate hazard labeling to minimize exposures. Thus, we combined the MITA with an *in vitro* sensitization test, the IL-8 Luc assay, recently approved as an OECD test guideline for *in vitro* skin sensitization testing (OECD TG442E)(OECD, 2017). We designated this combined assay ‘modified MITA’ (mMITA). We established a

data set of 60 chemicals by referring to the publication by Wagner et al. (Wagner et al., 2006) in which they examined 46 chemicals characterized to different degrees for their immunotoxic and immunomodulatory properties using the Fluorescent Cell Chip (FCP) assay. In addition, we also evaluated the chemicals listed in the case studies in the Guidance for Immunotoxicity Risk Assessment for Chemicals published by World Health Organization (WHO)/ and Meeting, 2012. Since there were several overlaps between the chemicals we examined in our previous publication and those examined by the FCP, our final data set comprised 60 chemicals evaluated by the mMITA (Kimura et al., 2018) (Table 24). Table 25 lists the chemicals that affected the normalized IL-2 luciferase activity in increasing order of their Lowest Observed Effect Level (LOEL), the results of the MITA evaluation (suppression (S), augmentation (A) or no effect (N)), the LOEL for each parameter of each chemical, and the results of the IL-8 Luc assay evaluation (sensitiser (S) and non-sensitiser (N)).

Table 24. Classification of chemicals by the mMITA in increasing order of the LOEL of the IL-2 Luc assay.

Table 25. The group by LOEL

Groups	Suppression of IL-2 promoter activity (LOEL μg/ml)
Group 1	LOEL<0.1
Group 2	0.1≤LOEL<1.0
Group 3	1.0≤LOEL<10
Group 4	10≤LOEL<1000
Group 5	None
Group 6	Augmentation

0.0/ of the LOEL means less than 0.001.

Using this data set, we first demonstrated a significant correlation between LOELs for the effects on the IL-2 luciferase assay and those on the IFN luciferase assay, and between LOELs for effects on the IL-1β luciferase assay and those on the IL-8 luciferase assay (Kimura et al., 2018) (Fig. 17). These results indicated that evaluations of the effects of chemicals on the IL-2 and IL-8 luciferase assays can provide immunotoxicological information almost equivalent to the evaluation of these chemicals using the IL-2, IFN-γ, IL-1β, and IL-8 luciferase assays.

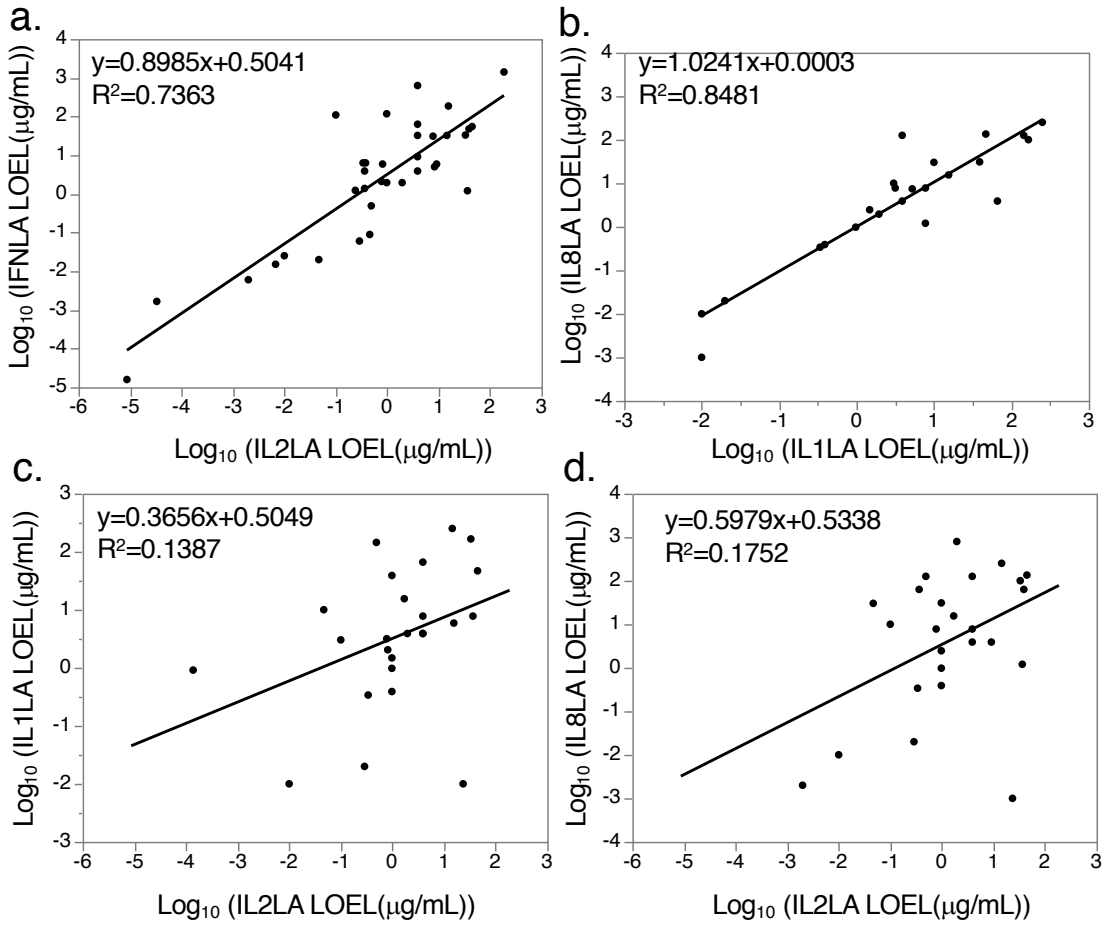

Fig. 17. The correlation between the LOEL for the 4 luciferase assays.

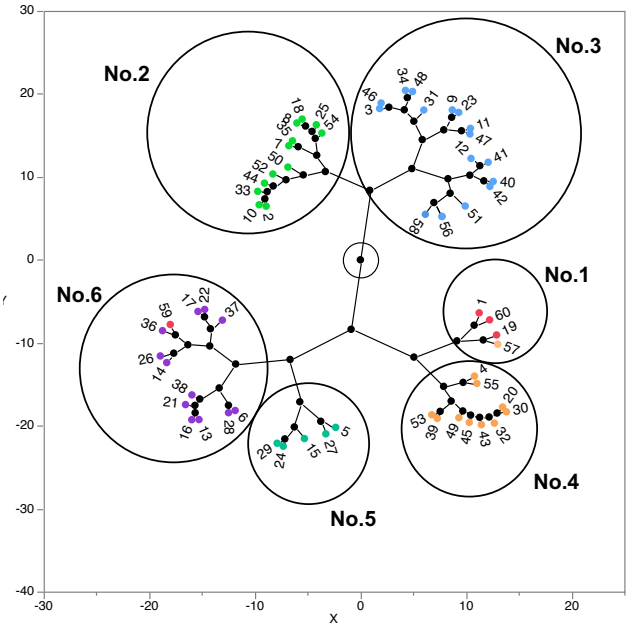
Next, we demonstrated that K-means clustering and hierarchical clustering of the 60 chemicals based on the LOEL for their effects on IL-2 and IL-8 promoter activities, and the judgment by the IL-8 Luc assay, resulted in the same 6-cluster solution: cluster 1 with preferential suppression of IL-8, cluster 2 with suppression of IL-2 and a positive IL-8 Luc assay result, cluster 3 with suppression of both IL-2 and IL-8, cluster 4 with no effects on IL-2 or IL-8 and a negative IL-8 Luc assay result, cluster 5 with suppression of both IL-2 and IL-8 and a negative IL-8 Luc assay result, and cluster 6 with preferential suppression of IL-2 (Kimura et al., 2018) (Figs. 18, 19 and 20). These data suggest that the mMITA is a promising novel high-throughput approach for detecting unrecognized immunological effects of chemicals and for profiling their

immunotoxic effects. The data obtained from these assays can be used by both industry and regulatory agencies to assess the immunotoxicity risks of chemicals. Toward this particular goal, the IL-2 Luc assay and the IL-8 or IL-1β Luc assay should be officially validated and a larger number of chemicals must be evaluated using the MITA to fully determine the potential and limits of this technique.



Cluster No	No	Chemicals

Fig. 18. Hierarchical clustering of 60 chemicals by the mMITA

Hierarchical clustering of 60 chemicals was performed for these 3 immunotoxic parameters and visualized using JMP pro 13.1.0. Table is the list of chemicals that belong to each cluster.

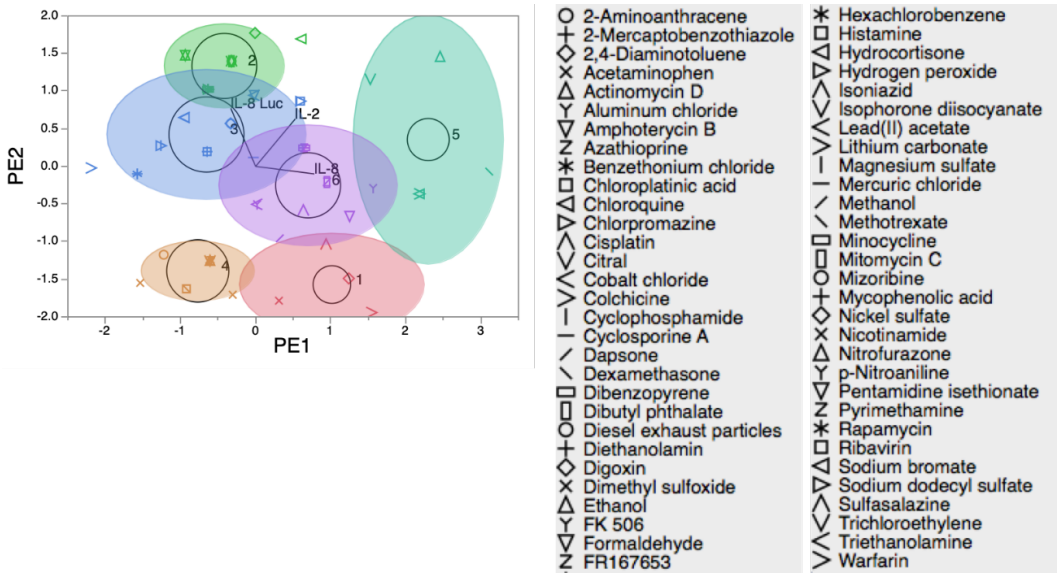

Fig. 19. K-means clustering analysis of chemicals by MITA

K-means clustering of 60chemicals was performed for these 3 immunotoxic parameters and visualized using JMP pro 13.1.0.

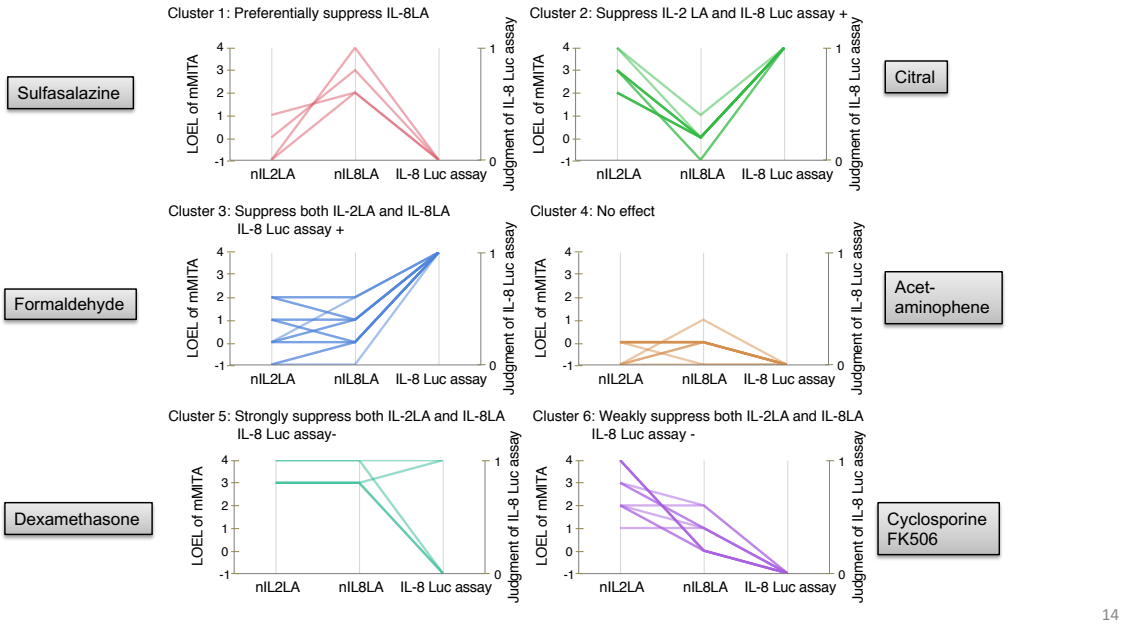

Fig. 20. Characteristics of each cluster and their representative chemicals

The scores for the LOEL of IL2LA, IL8LA and the IL8 Luc assay was plotted for each chemical belonging to different clusters.

10-9. The regulatory application of the IL-2 Luc assay.

The CAS REGISTRY^{SM} currently contains more than 130 million unique organic and inorganic chemical substances, such as alloys, coordination compounds, minerals, mixtures, polymers, and salts. Humans are exposed to many of these substances, which are present as environmental contaminants or used as food additives and drugs. Some of these compounds can target the immune system, resulting in adverse health effects such as the development of allergies, autoimmune disorders, increased susceptibility to infection and cancer, and other diseases. Accordingly, immunotoxicity, which is defined as the toxicological effects of xenobiotics on the function of the immune system, is a matter of serious concern to the public as well as regulatory agencies. To address these concerns, the World Health Organization published its Guidance for Immunotoxicity Risk Assessment for Chemicals (WHO). Currently, the assessment of chemical immunotoxicity relies mainly on animal models and assays that characterize immunosuppression and sensitization. However, animal studies have so many drawbacks, such as high cost, ethical concerns, and questionable relevance to risk assessment for humans, that they cannot screen immunotoxicity of more than 130 million chemicals. Therefore, it is an urgent matter to develop alternative testing methods and assessment strategies to reduce the use of laboratory animals and, if possible, replace animals used in scientific studies (Adler et al., 2011). So far, however, there is no OECD test guidelines to detect chemical immunotoxicity in vitro. Therefore, we would like to propose the IL-2 Luc assay, and the MITA in near future, as a screening toolbox of alternative test methods for immunotoxicity.

Finally, the VMT recommend that the proficiency chemicals (Appendix 15) to users and the performance standard chemicals (Appendix 16) to me-too validation study.

11. Conclusion

In this study, we conducted the validation study of the IL-2 Luc assay among the 4 luciferase assays that comprise the MITA. The results of both Phase I and Phase II studies satisfied the acceptance criteria for the validation study. Although the predictivity could not reach 80%, it may be acceptable when considering its applicability domain and limited target. So, we would like to propose the IL-2 Luc assay for the OECD test guideline of *in vitro* immunotoxicity test.

12. Acknowledgement

This validation study was supported by the Grants-in-Aid for the Ministry of Economy, Trade and Industry (METI), the Ministry of Health, Labor and Welfare (MHLW) and the Japanese Society for Alternatives to Animal Experiments (JSAAE). We gratefully acknowledge the voluntary works by the participated laboratories and the European Union Reference Laboratory for Alternatives to Animal Testing (EURL-ECVAM), and the NTP Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM).

1. Introduction

This protocol describes how to maintain the cells, how to prepare the test chemicals, and how to measure the luciferase activity of 2H4 cells transfected with 3 luciferase genes, stable luciferase green (SLG), stable luciferase orange (SLO) and stable luciferase red (SLR), under the control of IL-2, IFNγ and G3PDH promoters, respectively, for the Multi-Immuno Tox Assay.

(Kimura Y. et al. Evaluation of the Multi-Immuno Tox Assay composed of 3 human cytokine reporter cells by examining immunological effects of drugs *Toxicol in Vitro*, 28, 759-768, 2014)

2. Materials

2-1 Cells

2H4 (IL2-SLG、IFNγ-SLO、G3PDH-SLR)

The human acute T lymphoblastic leukemia cell line Jurkat was obtained from the American Type Culture Collection (Manassas, VA, USA). A Jurkat-derived IL-2 and IFNγ reporter cell line, 2H4,

that harbors the SLG, SLO and SLR luciferase genes under the control of the IL-2, IFNγ and GAPDH promoters, respectively, was established by Tsuruga Institute of Biotechnology, TOYOBO Co. Ltd. (Saito R. et al. Nickel differentially regulates NFAT and NF-κB activation in T cell signaling *Toxicology and Applied Pharmacology,* 254, 245–255, 2011)

2-2 Reagents and equipment

2-2-1 For maintenance of the 2H4 cells

RPMI-1640 (GIBCO Cat#11875-093, 500 mL)

FBS (Biological Industries Cat#04-001-1E Lot: 715004)

Antibiotic-Antimycotic (GIBCO Cat#15240-062)

HygromycinB (CAS:31282-04-9, Invitrogen Cat#10687-010)

G418 (CAS:108321-42-2, Nacalai Tesque Cat#16513-84)

Puromycin (CAS:58-58-2, InvivoGen Cat#ant-pr-1)

2-2-2 For chemical exposure, stimulation and solvents

Ionomycin (CAS:56092-82-1, Sigma Cat#I0634)

Phorbol 12-myristate 13-acetate (PMA) (CAS:16561-29-8, Sigma Cat#P8139)

Ethanol (e.g., Wako Cat#057-00456)

Dimethyl sulfoxide (DMSO) (CAS:67-68-5, Sigma Cat#D5879)

Distilled water (GIBCO Cat#10977-015)

2-2-3 For measurement of the luciferase activity

Triplu[®] Luciferase assay reagent (TOYOBO Cat#MRA-301)

2-2-4 Expendable supplies

T-75 flask tissue culture treated (e.g., Corning Cat#353136)

96 well μ clear black plate (flat-bottom, for measurement of the luciferase activity, e.g. Greiner Bio-one Cat#655090)

96 well clear plate (round-bottom, for preparation of chemicals and stimulants)

96 well assay block, 2 mL (e.g., Costar Cat#3960)

Seal for 96 well plate (e.g., Perkin Elmer TopSeal-A PLUS Cat#6050185, EXCEL Scientific SealMate Cat#SM-KIT-SP)

Reservoir

Pipette

2-2-5 Equipment for measurement of luciferase activity

Measuring device: a microplate-type luminometer with a multi-color detection system that can accept two optical filter

e.g. Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)

Optical filter: 560 nm long-pass filter and 600 nm long-pass filter

Measuring time: set at 1～5 sec/well measuring time

2-2-6 Others

Pipetman

8 channel or 12 channel pipetman (optimized for 10~100 μL)

Plate shaker (for 96 well plate)

CO_2 incubator (37°C, 5% CO_2)

Water bath

Cell counter: hemocytometer, trypan blue

2-3 Culture medium

2-3-1 A medium: for maintenance of 2H4 cells (500 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	440 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	50 mL
Antibiotic-Antimycotic	GIBCO #15240-062	100×	1×	5 mL
Puromycin	InvivoGen # ant-pr-1	10 mg/mL	0.15 μg/mL	7.5 μL
G418	Nacalai Tesque #16513-84	50 mg/mL	300 μg/mL	3 mL
HygromycinB	Invitrogen #10687-010	50 mg/mL	200 μg/mL	2 mL

2-3-2 B medium: for luciferase assay (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL

2-3-3 C medium: for thawing 2H4 cells (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	26.7 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL
Antibiotic-Antimycotic	GIBCO #15240-062	100×	1×	0.3 mL

2-4 Preparation of the stimulant of 2H4

2-4-1 Phorbol 12-myristate 13-acetate (PMA)

Reagent	Company	Concentration of the stock solution	Final concentration
Phorbol 12-myristate 13-acetate (PMA)	Sigma #P8139	2 mM	25 nM
DMSO	Sigma #D5789		

Dissolve 1 mg PMA using DMSO 811 μL, dispend at 5 μL/tube and store at freezer at -30°C. Use these stocks within 6 months after dissolution.

2-4-2 Ionomycin

Reagent	Company	Concentration of the stock solution	Final concentration
Ionomycin	Sigma # I0634	2 mM	1 μM
Ethanol	Wako #057-00456		

Dissolve 1mg Ionomycin using ethanol 669.3 μL, dispend at 30 μL/tube and store at freezer at -30°C. Use these stocks within 6 months after dissolution.

3. Cell culture

3-1 Thawing of 2H4 cells

Pre-warm 9 mL of C medium in a 15 mL polypropylene conical tube in a 37°C water bath (for centrifugation) and 15 mL of C medium in a T-75 Flask at 37°C in a 5% CO_2 incubator (for culture).

Thaw frozen cells ($2x10^6$ cells / 0.5 mL of freezing medium) in a 37°C water bath, then add to a 15 mL polypropylene conical tube containing 9 mL of pre-warmed C medium. Centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in 15 mL of pre-warmed C medium in a T-75 Flask. Cells are incubated at 37°C, 5% CO_2.

3-2 Maintenance of 2H4 cells

Pre-warm the A medium in a T-75 Flask at 37°C in a 5% CO_2 incubator. The culture medium should be changed to the A medium 3 or 4 days after thawing. At that time, count the number of cells, centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in pre-warmed the A medium in a T-75 Flask. Cells are passaged at $3x10^5$/mL and incubated at 37°C, 5% CO_2.

The interval between subcultures should be 3~4 days. Cells can be used between one and six weeks after thawing.

4. Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (2.0 x 10^7 cells for two chemicals are required, but to have some leeway, 3.0 x 10^7 cells for two chemicals should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 4×10^6/mL. Transfer the cell suspension to a reservoir, and add 50 µL of cell suspension to each well of a 96 well µclear black plate (flat bottom) using an 8 channel or 12 channel pipetman. (cf. Figure 2)

5. Preparation of chemicals and cell treatment with chemicals

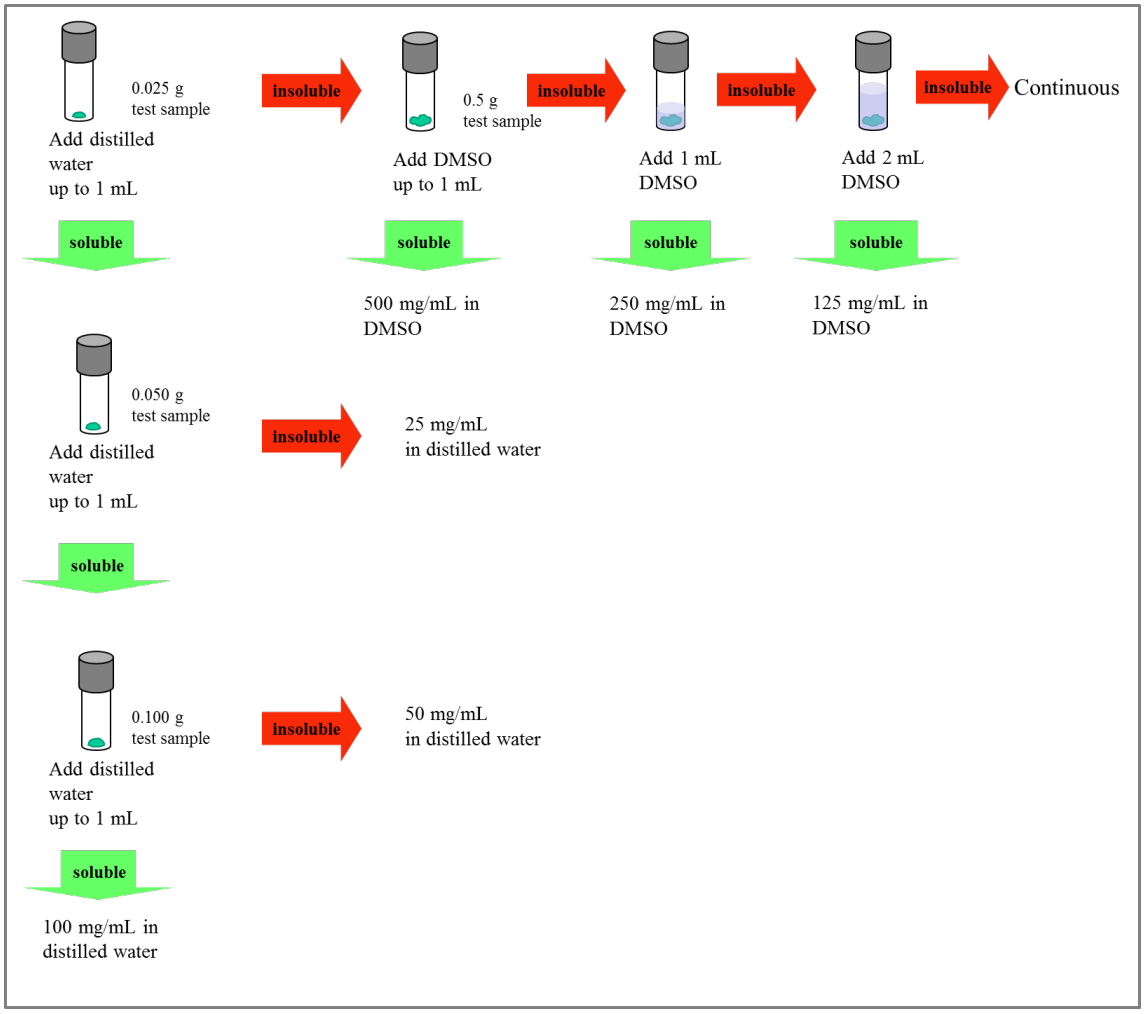
5-1 Dissolution by vehicle (cf. Figure 3)

Dissolve the chemical first in distilled water. Namely, weigh 0.025 g of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is soluble at 25 mg/mL, weigh 0.050 g of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is not soluble at 50 mg/mL, 25 mg/mL is the highest soluble concentration. If the chemical is soluble at 50 mg/mL, weigh 0.100 g of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is not soluble at 100 mg/mL, 50 mg/mL is the highest soluble concentration. If the chemical is soluble at 100 mg/mL, 100 mg/mL is the highest soluble concentration.

If the chemical is not soluble in water, the chemical should be dissolved in DMSO at 500 mg/mL. Namely, weigh 0.5 g of the test chemical in volumetric flask and add DMSO up to 1 mL.
If the chemical is not soluble at 500 mg/mL, the highest soluble concentration should be determined by diluting the solution from 500 mg/mL at a common ratio of two (250 mg/mL → 125 mg/mL → continued if needed) with DMSO.

Sonication and vortex may be used if needed, and attempt to dissolve the chemical for at least 5 minutes. Being soluble should be confirmed by centrifugation at 15,000 rpm (≈20,000 x g) for 5 min and absence of precipitation. The chemical should be used within 4 hours after being dissolved in distilled water or DMSO.

Figure 3



In the first experiment (1st experiment), when the chemical is prepared in distilled water, conduct 10 serial dilutions at a common ratio of 2 from the highest concentration using distilled water. When the chemical is prepared as a DMSO solution, conduct 10 serial dilutions at a common ratio of 2 from the highest concentration using DMSO.

In the second to fourth experiment (2nd to 4th experiment), determine the minimum concentration at which I.I.-SLR-LA (mentioned later in **10**) became lower than 0.05 in the 1st experiment, use the concentration one step (2-times) higher than this determined concentration as the highest concentration of the chemical to examine, and conduct 10 serial dilutions at a common ratio of 2 from the highest concentration. If I.I.-SLR-LA did not become lower than 0.05 or became lower than 0.05 at the highest concentration in the 1st experiment, conduct 10 serial dilutions at a common ratio of 2 from the highest concentration in the 1st experiment.

For example, in Figure 3 below, the minimum concentration at which I.I.-SLR-LA became lower than 0.05 is 1.95 μg/ml. The highest concentration of the chemical to examine is the concentration one step (2-times) higher than 1.95 μg/ml, which is 3.91 μg/ml.

In Figure 4 below, I.I.-SLR-LA did not become lower than 0.05. In such a case, the highest concentration of the chemical to examine is the highest concentration in the 1st experiment, namely 125 μg/ml.

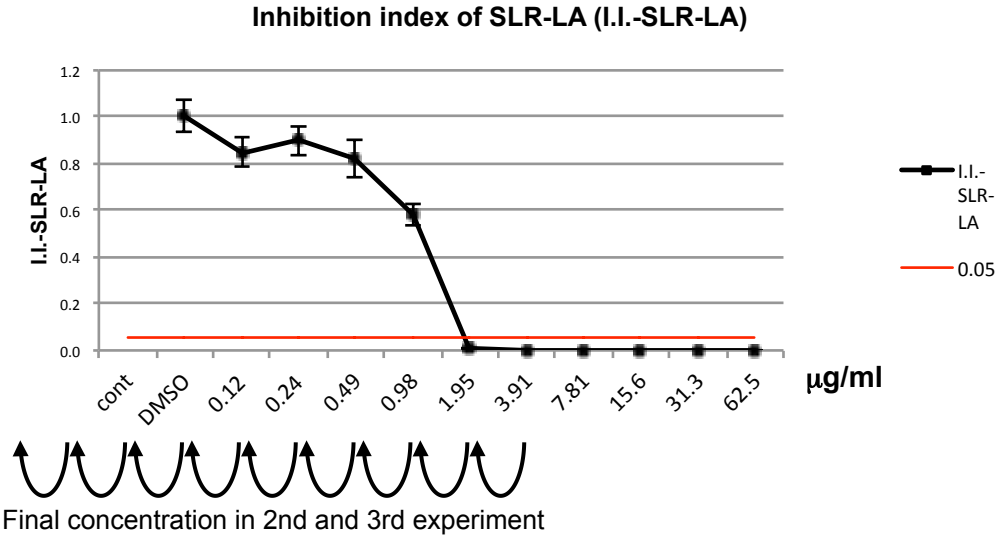


Figure 3.

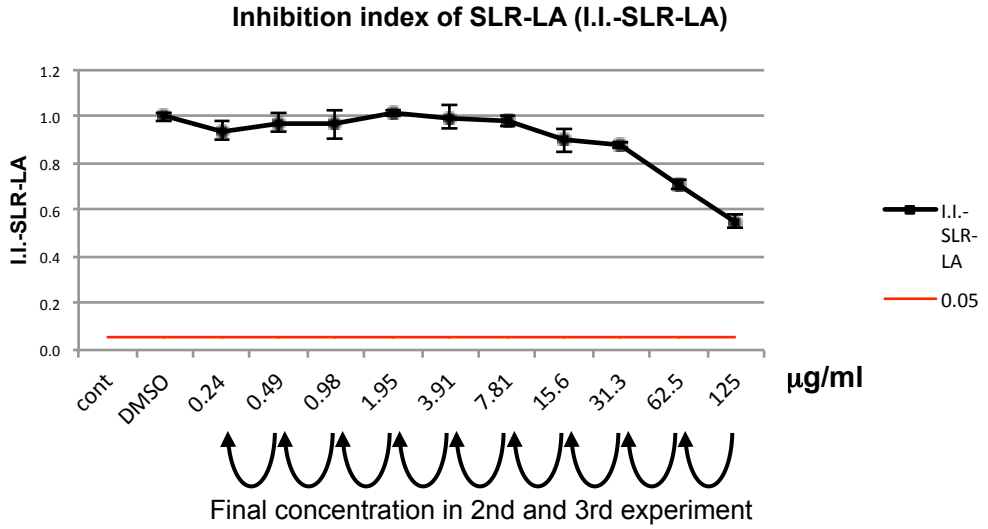

Figure 4

5-2 When the chemical is prepared in distilled water

If the chemical is prepared at a lower concentration, use the prepared concentration instead of the 100 mg/mL distilled water solution.

5-2-1 Arrangement of chemicals and vehicle

Add 100 µL of the 100 mg/mL distilled water solution of the chemical to well #A12, and 50 µL of the distilled water to wells #A1-#A11 of the 96 well clear plate (round bottom).

5-2-2 Serial dilution

Conduct 9 serial dilutions at a common ratio of 2 as indicated in Figure 4 from well #A11 to well #A3. Transfer 50 µL to the next (left) well. (cf. Figure 4)

5-2-3　2 step dilution

Add 20 µL of the diluted chemical to 480 µL of the B medium prepared in the assay block. And add 50 µL to 2H4 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 1 hour (37°C, CO_2, 5%) (cf. Figure 5-7).

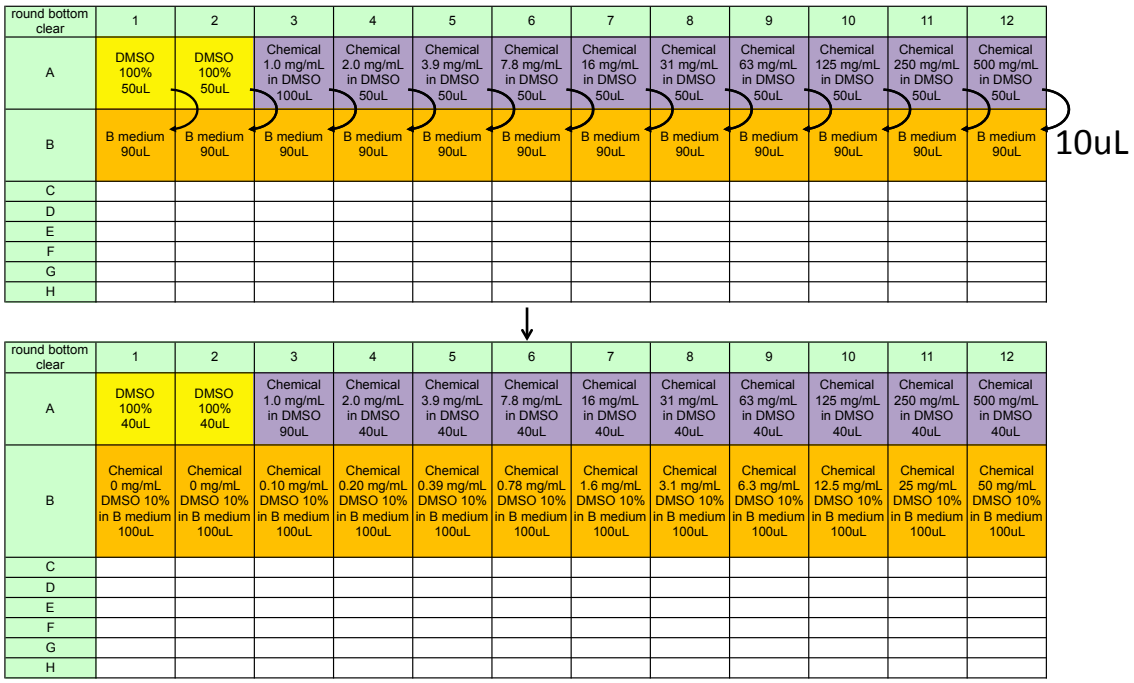
5-3-3 Dilution of DMSO solution with the B medium

Dilute 10 μL of the DMSO solution of the chemical in wells #A1-#A12 with 90 μL of the B medium using an 8-12 channel pipetman. (cf. Figure 9)

Figure 9



5-3-4　2 step dilution

Add 10 μL of the diluted chemical to 490 μL of the B medium prepared in the assay block. And add 50 μL to 2H4 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Manipulate the procedures from 5-3-3 to 5-3-4 as quickly as you can, and do not leave a long time at step after 5-3-3 or Figure 10. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 1 hour (37°C, CO_2, 5%) (cf. Figure 10-12).

6. Preparation of the stimulant (PMA/ionomycin) and addition to 2H4

6-1 Material

・2 mM PMA stock

・2 mM Ionomycin stock

・B medium

・Ethanol

6-2 Preparation of 100 μM PMA

Dilute 2 mM PMA stock with the B medium as follows (20 times, final concentration is 100 μM).

2 mM PMA	B medium	Total	final concentration
5 μL	95 μL	100 μL	100 μM

6-3 Preparation of control and x10 PMA/ionomycin solution

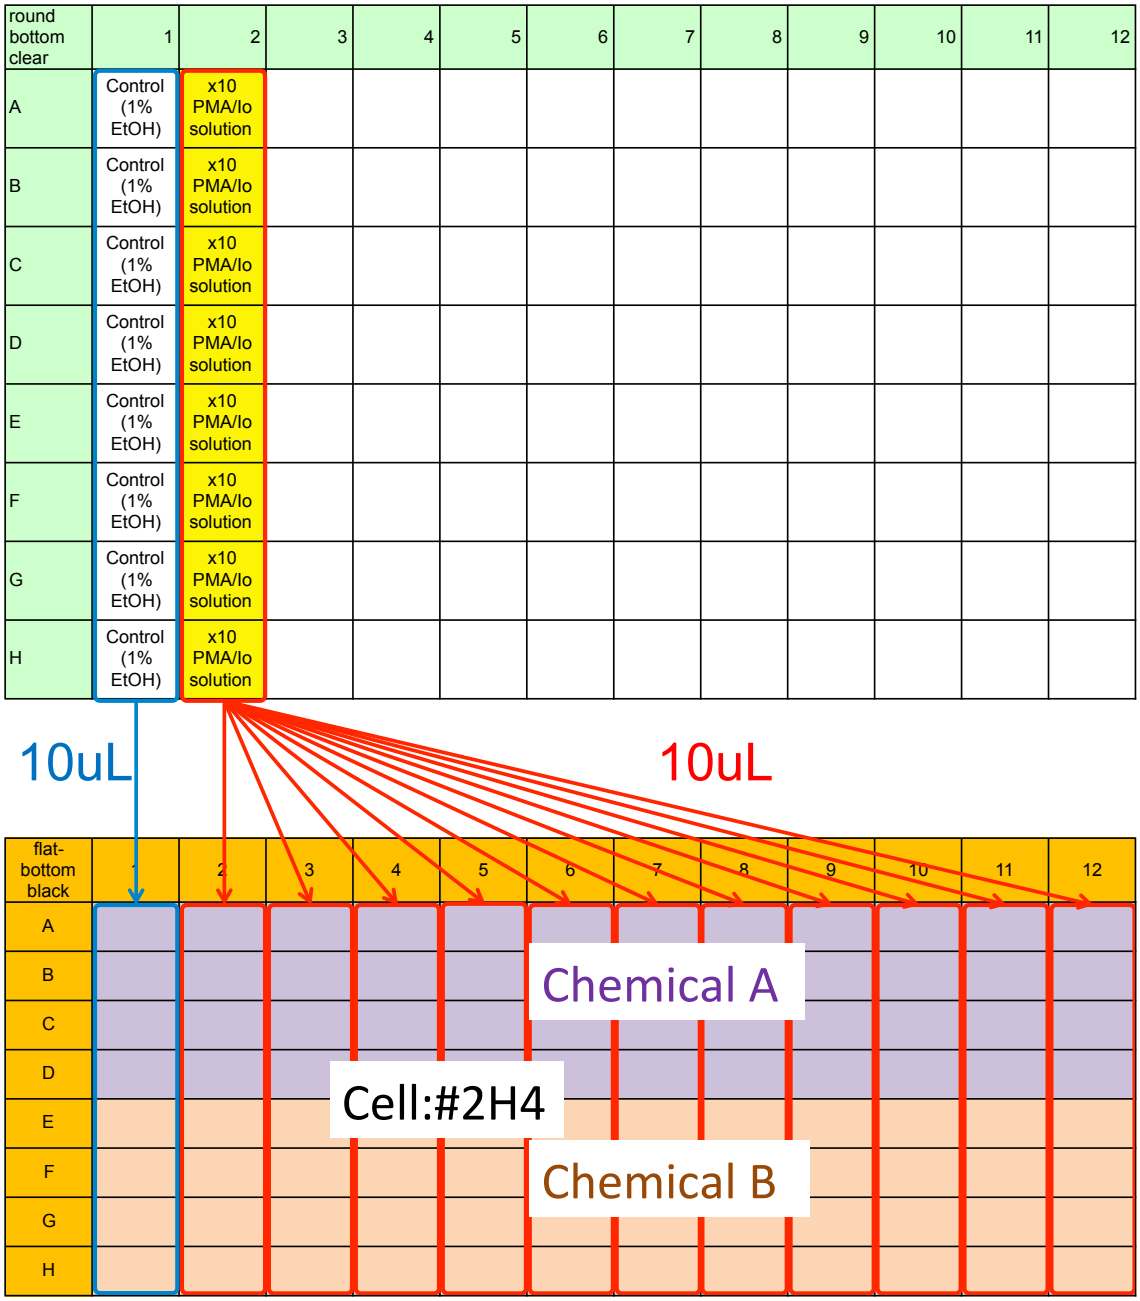
Dilute ethanol, 2 mM ionomycin and 100 μM PMA with the B medium to prepare control or x10 PMA/ionomycin solution. Add the control to well #A1-#H1 of the 96 well clear plate (round bottom), and add x10 PMA/ionomycin solution to wells #A2-#H2 of the 96 well clear plate (round bottom).

	B medium	2 mM Ionomycin	100 μM PMA	Ethanol	Total
Control	995 μL	-		5 μL	1000 μL
x10 PMA/ionomycin solution	2382 μL	12 μL	6 μL	-	2400 μL

6-4 Addition of PMA/ionomycin to 2H4

One hour after the addition of chemicals, add 10 μL of control or PMA/ionomycin solution to the cells (#A1-#H1 or #A2-#H12, respectively) using an 8 channel or 12 channel pipetman after pipetting 20 times. Make sure that the apex of the tip is dipped into the medium. Change tips every line you add. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 6 hour (37°C, CO_2, 5%). (cf. Figure 13)

Figure 13



7. Control

7-1 Preparing control chemical (dexamethasone, cyclosporine A)

7-1-1 Preparing dexamethasone stock

Reagent	Company	Concentration of the stock solution	Preparing concentration	Final concentration
Dexamethasone-water soluble	Sigma #D2915-100MG	2.5 mg/mL	2.5 mg/mL	50 μg/mL
Distilled water	GIBCO Cat#10977-015			

Dissolve 100 mg of Dexamethasone-water soluble with distilled water 40 mL, dispend at 50 μL/tube and store a freezer at -30°C.

7-1-2 Preparing cyclosporine A stock

Reagent	Company	Concentration of the stock solution	Preparing concentration	Final concentration
Cyclosporine A	Sigma #C1832-5MG	100 μg/mL	100 μg/mL	100 μg/mL
DMSO	Sigma #D5789			

Dissolve 5 mg of cyclosporine A with DMSO 50 mL, dispend at 50 μL/tube and store a freezer at -30°C.

7-2 Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (5.0 x 10^6 cells are required, but to have some leeway, 7.5 x 10^6 cells should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 4×10^6/mL. Transfer the cell suspension to a reservoir, and add 50 µL of cell suspension to each well of a 96 well µclear black plate (flat bottom) using an 8 channel or 12 channel pipetman. (cf. Figure 14)

Figure 14

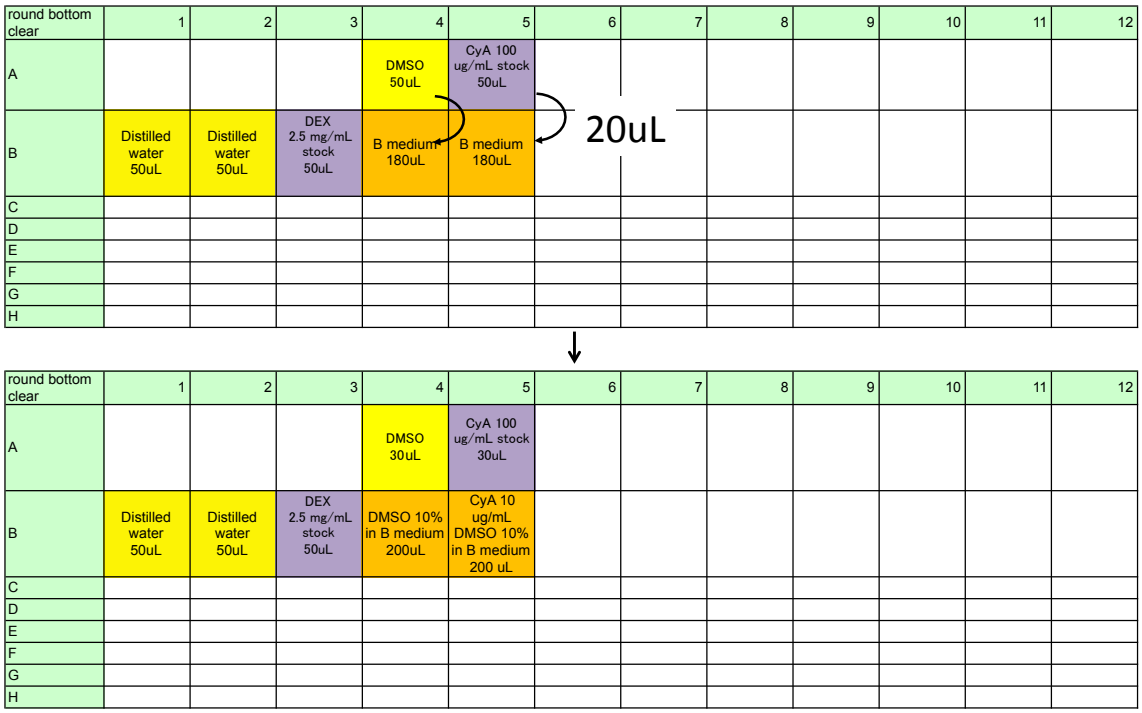
7-3 Arrangement of chemicals and vehicle

Add DMSO 50 µL to #A4, 100 µg/mL cyclosporine A stock 50 µl to #A5, distilled water 50 µl to #B1 and #B2, 2.5 mg/ml dexamethasone stock 50 µl to #B3 and the B medium 180 µl to #B4 and #B5 of the 96 well clear plate (round bottom). (cf. Figure 15)

7-4 Dilution with the B medium

Dilute DMSO in #A4 and cyclosporine A DMSO solution in #A5 by adding 20 µL to the B medium in #B4 and #B5, respectively. (cf. Figure 15)

Figure 15



7-5　　2 step dilution

Add 20 μL of the diluted chemical or vehicle to 480 μL (1-3 lanes) or 980 μL (4-5 lanes) of the B medium prepared in the assay block. And add 50 μL to 2H4 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Manipulate the procedures from 7-4 to 7-5 as quickly as you can, and do not leave a long time at step after 7-4 or Figure 16. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 1 hour (37°C, CO_2, 5%). (cf. Figure 16-18)

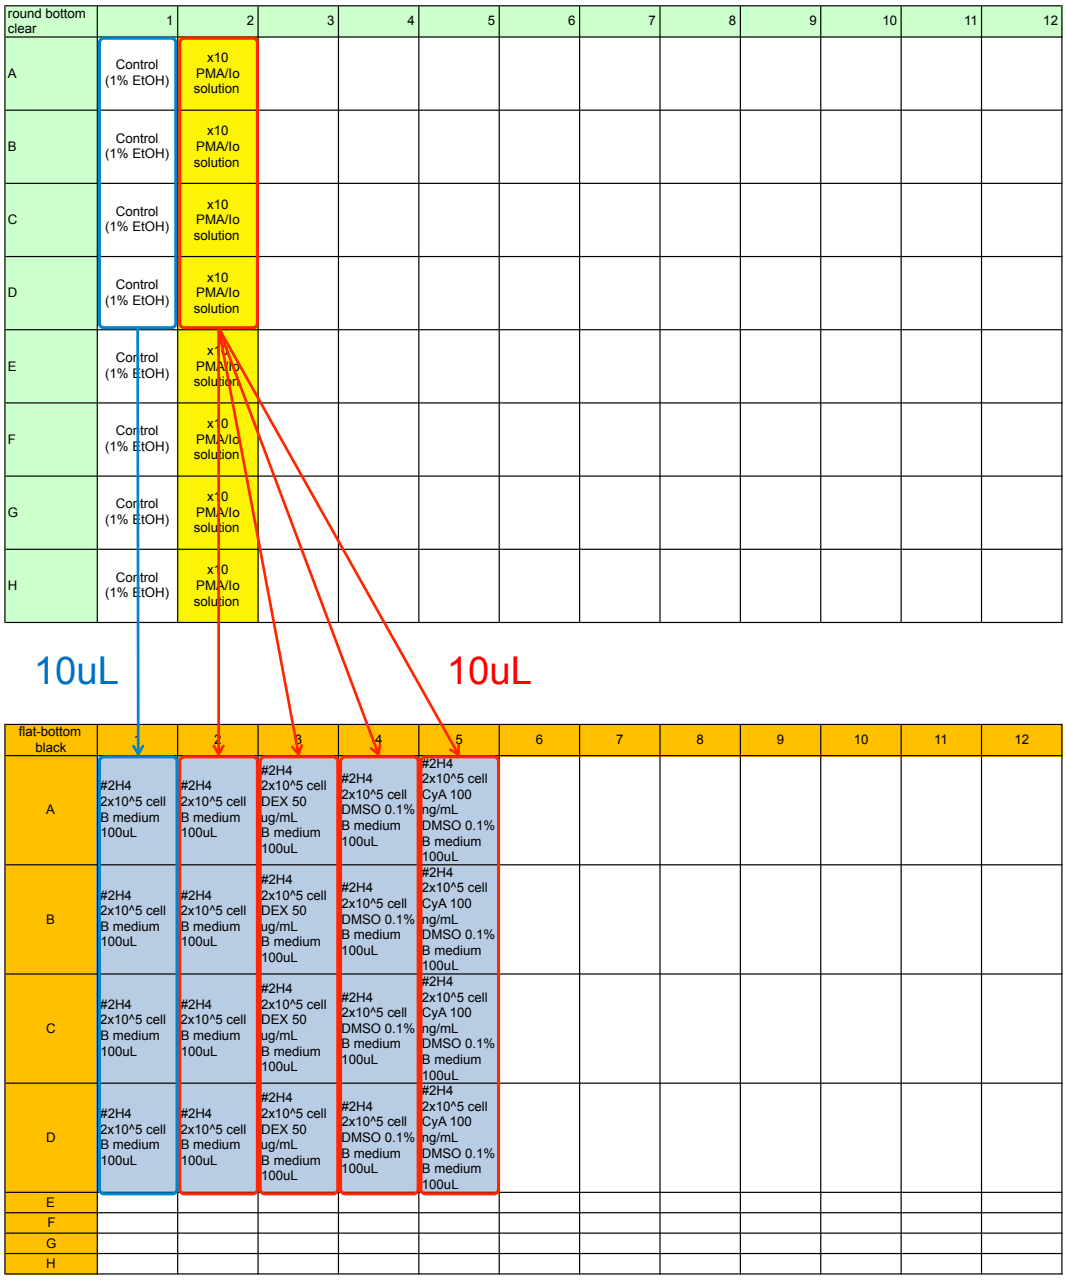
7-6 Addition of PMA/ionomycin to 2H4

One hour after the addition of dexamethasone and cyclosporine A, add 10 µL of control or PMA/ionomycin solution prepared in §6-3 to the cells (#A1-#D1 or #A2-#D5, respectively) using an 8 channel or 12 channel pipetman after pipetting 20 times. Make sure that the apex of the tip is

dipped into the medium. Change tips every line you add. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 6 hour (37°C, CO_2, 5%). (cf. Figure 19)

Figure 19



8. Calculation of the transmittance factors

Color discrimination in multi-color reporter assays is generally achieved using detectors (luminometer and plate reader) equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmittance factors of these filters for each bio-luminescence signal color must be calibrated prior to all experiments by following the protocols below.

8-1 Reagents

Single reference samples:

Lyophilized luciferase enzyme reagent for stable luciferase green (SLG)

Lyophilized luciferase enzyme reagent for stable luciferase orange (SLO)

Lyophilized luciferase enzyme reagent for stable luciferase red (SLR)

Assay reagent:

Tripluc® Luciferase assay reagent（TOYOBO Cat#MRA-301）

B medium: for luciferase assay (30 mL, stored at 2- 8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL

8-2 Preparation of luminescence reaction solution

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature either in a water bath or at ambient air temperature. Power on the luminometer 30 min before starting the measurement to allow the photomultiplier to stabilize.

Add 200 μL of 100 mM Tris-HCl (pH8.0) contains 10 % glycerol to each tube of lyophilized reference sample to dissolve the enzymes, divide into 10 μL aliquots in 1.5 mL disposable tubes and store in a freezer at -80°C. The stored frozen solution of the reference samples can be used for up to 6 months.

Add 1 mL of the B medium to each tube of frozen reference sample (10 μL sample per tube). Keep the reference samples on ice to prevent deactivation.

8-3 Bioluminescence measurement

Transfer 100 μL of the diluted reference samples to a black 96 well plate (flat bottom) as shown below.

Figure 20

flat-bottom black	1	2	3	4	5	6	7	8	9	10	11	12
A												
B	SLG 100 µL	SLG 100 µL	SLG 100 µL

E												
F	SLR 100 µL	SLR 100 µL	SLR 100 µL									
G												
H												

Transfer 100 µL of pre-warmed Tripluc to each well of the plate containing the reference sample using a pipetman. Shake the plate for 10 min at room temperature (about 25°C) using a plate shaker. Remove bubbles in the solutions in wells if they appear. Place the plate in the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1, F2) of the optical filters. An example of the raw output data is shown below.

Six transmittance factors of the optical filters were calculated as follow:

Transmittance factor (κG_{R56})=$\frac{\#B1 \text{ of } F1+ \#B2 \text{ of } F1+ \#B3 \text{ of } F1}{\#B1 \text{ of } F0+ \#B2 \text{ of } F0+ \#B3 \text{ of } F0}$

Transmittance factor (κO_{R56})=$\frac{\#D1 \text{ of } F1+\#D2 \text{ of } F1+\#D3 \text{ of } F1}{\#D1 \text{ of } F0+\#D2 \text{ of } F0+\#D3 \text{ of } F0}$

Transmittance factor (κR_{R56})= $\frac{\#F1 \text{ of } F1+\#F2 \text{ of } F1+\#F3 \text{ of } F1}{\#F1 \text{ of } F0+\#F2 \text{ of } F0+\#F3 \text{ of } F0}$

Transmittance factor (κG_{R60})=$\frac{\#B1 \text{ of } F2+ \#B2 \text{ of } F2+ \#B3 \text{ of } F2}{\#B1 \text{ of } F0+ \#B2 \text{ of } F0+ \#B3 \text{ of } F0}$

Transmittance factor (κO_{R60})=$\frac{\#D1 \text{ of } F2+\#D2 \text{ of } F2+\#D3 \text{ of } F2}{\#D1 \text{ of } F0+\#D2 \text{ of } F0+\#D3 \text{ of } F0}$

Transmittance factor (κR_{R60})=$\frac{\#F1 \text{ of } F2+\#F2 \text{ of } F2+\#F3 \text{ of } F2}{\#F1 \text{ of } F0+\#F2 \text{ of } F0+\#F3 \text{ of } F0}$

In the case shown above,

Transmittance factors (κG_{R56})=$\frac{1269550+1257268+1289562}{3757015+3716611+3810382}$=0.338

Transmittance factors (κO_{R56})=$\frac{808550+813160+754174}{1202691+1210208+1122295}$=0.672

Transmittance factors (κR_{R56})=$\frac{2193723+1968240+1853873}{2465453+2207572+2077689}$=0.891

Transmittance factors (κG_{R60})= $\frac{236478+234079+240876}{3757015+3716611+3810382}$=0.06

Transmittance factors (κO_{R60})=$\frac{235121+235878+217432}{1202691+1210208+1122295}$=0.195

Transmittance factors (κR_{R60})=$\frac{1585258+1420099+1339265}{2465453+2207572+2077689}$=0.644

Calculated transmittance factors are used for all the measurements executed using the same luminometer.

Input the transmittance factors to #C6-#E7 of the “Data Input” sheet of the Data sheet as follow.

9. Measurement

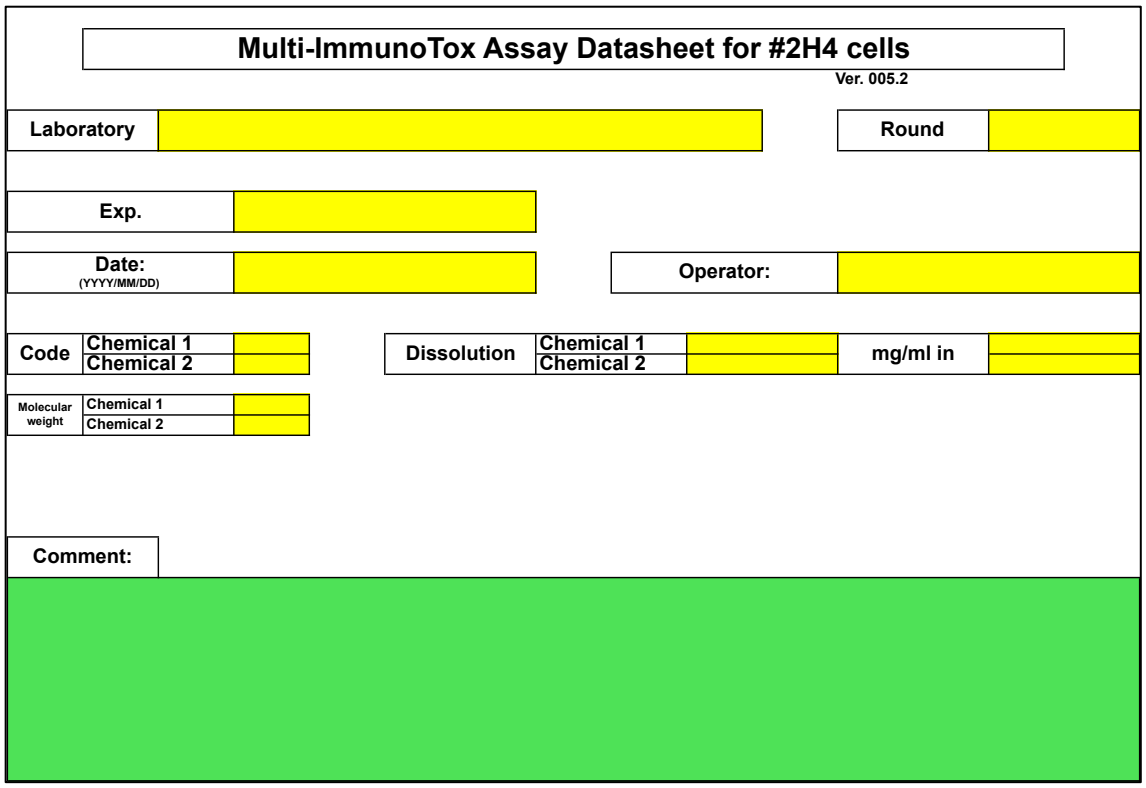
Please refer Appendix 1 for the principle of measurement of luciferase activity.

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature either in a water bath or at ambient air temperature. Power on the luminometer 30 min before starting the measurement to allow the photomultiplier to stabilize.

Transfer 100 µL of pre-warmed Tripluc from the reservoir to each well of the plate containing the reference sample using an 8 channel or 12 channel pipetman. Shake the plate for 10 min at room temperature (about 25°C) on a plate shaker. Remove bubbles in the solutions in the wells if they appear. Place the plate in the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence of (F0) and presence (F1, F2) of the optical filters.

1st. Add the information regarding the name of laboratory, the round of experiments if multiple experimental sets are performed, the experiment number, date, the operator, chemical codes, dissolved in distilled water or DMSO, the prepared concentration, molecular weight of the chemicals and comments if any to Face Sheet of the data sheet.

Figure 24 “Face Sheet” of the data sheet



2nd. Copy the results of the F0, F1 and F2 measurements (values are expressed as counts) and paste them into the appropriate area in the “Data Input” sheet of the data sheet shown below. In addition, input the transmittance factors calculated in "§5. Calculation of the transmittance factors" to #C6-

#E7 of the “Data Input” sheet.

10. Data analysis

Definition of the parameters used in the Multi-Immuno Tox assay

SLG-luciferase activity (SLG-LA) : Luciferase activity of stable luciferase green
(Under the control of IL-2 promoter)

SLO-luciferase activity (SLO-LA) : Luciferase activity of stable luciferase orange
(Under the control of IFN-γ promoter)

SLR-luciferase activity (SLR-LA) : Luciferase activity of stable luciferase red
(Under the control of G3PDH promoter)

Normalized SLG-LA (nSLG-LA) : =(SLG-LA)/(SLR-LA)

Normalized SLO-LA (nSLO-LA) : =(SLO-LA)/(SLR-LA)

Inhibition index of SLR-LA (I.I.-SLR-LA) : The cytotoxic effect of chemicals
=(SLR-LA of 2H4 treated with chemicals)/(SLR-LA of untreated 2H4)

%suppression : The effect of chemicals on IL-2 or IFN-γ promoter
=(1-(nSLG-LA or nSLO-LA of 2H4 treated with chemicals)
/(nSLG-LA or nSLO-LA of non-treated 2H4)) x 100

11. Criteria

11-1 Acceptance criteria

The following acceptance criteria should be satisfied when using the Multi-Immuno Tox Assay method.

If Fold induction of nSLO-LA of PMA/Ionomycin wells without chemicals (=(nSLO-LA of 2H4 cells treated with PMA/Ionomycin) / (nSLO-LA of non-treated 2H4 cells)) demonstrate less than 3.0, the results obtained from the plate containing the control wells should be rejected.

11-2 Criterion

The experiments are repeated until two consistent positive (negative) results or two consistent “no effect results” are obtained. When two consistent results are obtained, the chemicals are judged as the obtained consistent results.

Identification of immunotoxicant is evaluated by the mean of %suppression and its 95% simultaneous confidence interval.

In each experiment, when the chemicals clear the following 3 criteria, they are judged as suppressive or stimulatory. Otherwise, they are judged as no effect chemicals.

1. The mean of %suppression is $\geq$ 35 (suppressive) or $\leq$ -35 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.

2. The result shows two or more consecutive statistically significant positive (negative) data or one statistically significant positive (negative) data with a trend in which at least 3 consecutive data increase (decrease) in a dose dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.

3. The results are judged using only data obtained in the concentration at which I.I.-SLR-LA is $\geq$ 0.05.

Appendix 5 Principle of measurement of luciferase activity

MultiReporter Assay System -Tripluc- can be used with a microplate-type luminometer with a multi-color detection system, which can equip two optical filters (e.g. Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)). The optical filters used in measurement are a 560 nm long-pass filter and a 600 nm long-pass filter.

(1) Measurement of three-color luciferase with two optical filters.

This is an example using Phelios AB-2350 (ATTO). This luminometer equips a 560 nm long-pass filter (560 nm LP, Filter 1) and a 600 nm long pass filter (600 nm LP, Filter 2) for optical isolation.

First, using luciferase enzyme reagent of SLG (λmax = 550 nm), SLO (λmax = 580 nm) and SLR (λmax = 630 nm), measure i) the intensity of light without filter (all optical), ii) the intensity of 560 nm LP (Filter 1) transmitted light iii) the intensity of 600 nm LP (Filter 2) transmitted light, and calculate the coefficient factor listed below.

Coefficient factor		Abbreviation	Definition
SLG	Filter 1 transmittance factor	κG_{R56}	The intensity of 560 nm LP (Filter 1) transmitted SLG / the intensity of SLG without filter (all optical)
	Filter 2 transmittance factor	κG_{R60}	The intensity of 600 nm LP (Filter 2) transmitted SLG / the intensity of SLG without filter (all optical)
SLO	Filter 1 transmittance factor	κO_{R56}	The intensity of 560 nm LP (Filter 1) transmitted SLO / the intensity of SLO without filter (all optical)
	Filter 2 transmittance factor	κO_{R60}	The intensity of 600 nm LP (Filter 2) transmitted SLO / the intensity of SLO without filter (all optical)
SLR	Filter 1 transmittance factor	κR_{R56}	The intensity of 560 nm LP (Filter 1) transmitted SLR / the intensity of SLR without filter (all optical)
	Filter 2 transmittance factor	κR_{R60}	The intensity of 600 nm LP (Filter 2) transmitted SLR / the intensity of SLR without filter (all optical)

When the intensity of SLG, SLO and SLR in test sample are defined as G, O and R, respectively, i) the intensity of light without filter (all optical): F0, ii) the intensity of 560 nm LP (Filter 1) transmitted light and iii) the intensity of 600 nm LP (Filter 2) transmitted light are described as below.

$F0=G+O+R$

$F1=\kappa G_{R56} \times G + \kappa O_{R56} \times O + \kappa R_{R56} \times R$

$F2=\kappa G_{R60} \times G + \kappa O_{R60} \times O + \kappa R_{R60} \times R$

These formulas can be rephrased as follows

$$\begin{pmatrix} F0 \\ F1 \\ F2 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \kappa G_{R56} & \kappa O_{R56} & \kappa R_{R56} \\ \kappa G_{R60} & \kappa O_{R60} & \kappa R_{R60} \end{pmatrix} \begin{pmatrix} G \\ O \\ R \end{pmatrix}$$

Then using calculated coefficient factors and measured F0, F1 and F2, you can calculate G, O and R-value as follows.

$$\begin{pmatrix} G \\ O \\ R \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \kappa G_{R56} & \kappa O_{R56} & \kappa R_{R56} \\ \kappa G_{R60} & \kappa O_{R60} & \kappa R_{R60} \end{pmatrix}^{-1} \begin{pmatrix} F0 \\ F1 \\ F2 \end{pmatrix}$$

This calculation can be performed using the functions "MININVERSE" and "MMULT" in Microsoft Excel. These calculations are integrated in the Data Sheet.

Appendix 6　Validation of reagents and equipment

5-1 Measurement of transmittance of optical filter for multicolor measurement

For color discriminations in the multi-color reporter assay, detectors (luminometer and plate reader) are usually equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmittance factors of these filters for each bioluminescence signal color have to be calibrated prior to all experiments by following the protocols below.

5-1-1　Reagents

・Single reference samples:

Lyophilized luciferase enzyme reagent of SLG

Lyophilized luciferase enzyme reagent of SLO

Lyophilized luciferase enzyme reagent of SLR

・Assay reagent:

Tripluc® Luciferase assay reagent（TOYOBO Cat#MRA-301）

・B medium: for luciferase assay (30 mL, stored at 2 – 8°C)

Reagent	Company	Conc.	Final conc. in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL

5-1-2 Calibration

5-1-2-1 Preparation of luminescence reaction solution

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature by bathing in water or ambient air. Start the luminometer 30 min before starting the measurement for stabilization of the photomultiplier.

Add 200 μL of 100 mM Tris-HCl (pH8.0) contains 10% glycerol to each tube of the lyophilized reference samples to dissolve the enzymes, followed by separating them into 1.5 mL disposable tubes at 10 μL each and storing in a freezer at -80°C. The stored frozen solution of the reference samples can be used for one half year.

Add 1 mL of the B medium to each tube of the frozen reference sample (10 μL in a tube) and label them as SLG1/1, SLO1/1 and SLR1/1. Keep the reference samples on ice to prevent deactivation.

Prepare dilution series of the single reference samples of SLG, SLO and SLras follows. Dilute 0.3 mL of each 1/1 solution with 0.9 mL of the B medium to make SLG1/4, SLO1/4 and SLR1/4. In the same manner, prepare 1/16 and 1/64 solution of each. Keep diluted reference samples on ice.

5-1-2-2 Bioluminescence measurement

Transfer 100 μL of the diluted reference samples to a black 96 well plate (flat bottom) as shown below.

Figure 27

G												
H												

Transfer 100 μL of pre-warmed Tripluc to each well containing the reference samples of the plate using a pipetman. Shake the plate for 10 min at room temperature (about 25°C) with a plate shaker. Remove bubbles on the solutions in wells if they appear. Place the plate into the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1, F2) of the optical filters.

Copy the results of the F0, F1 and F2 measurement (values are expressed as counts) and paste it to the appropriate area in the “Data Input” sheet of the data sheet for data analyses shown below.

Record all the results for quality control.

5-2 Quality control of equipment

In order to confirm the detector stability as the quality control, the reference luciferase sample, optical property, the protocol described here should be performed at the beginning of the experiments every day.

5-2-1 Light source

LED Plate: Reference LED light source plates equipped with stabilized red, green, and blue LEDs are commercially available. For example,

TRIANT® (wSL-0001) by ATTO (Tokyo, Japan)

L12367 by Hamamatsu Photonics (Shizuoka, Japan)

5-2-2 Data collection (an example using TRIANT® by ATTO)

1) Start luminometer 30 min before starting the measurement for stabilization of the photomultiplier.
2) Start LED plate and select “PMT” mode.
3) Select three-color (BRG) mode and adjust light intensity to 1/10 (10E-1).
4) Place the LED plate into the luminometer. Light intensity is measured for 3 sec each in the absence (F0) and presence (F2) of the optical filter.
5) Blue, green, and red LEDs are located at the position of #F6, #E6, and #D6, respectively. Copy

the collected data of each position to the appropriate area on Sheet “LED” in the excel file of the data sheet.

6) Check the photo-detector performance by comparing with old data of the LED plate. For quality control purpose, every collected data should be recorded.

7) LED plate data typically fluctuates up to 1.5% (σ). Disagreement to the old data should be less than 3×σ (= 4.5%).

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Female B6C3F1 mice were orally dosed with 25, 50, or 100 mg/kg DAT for 14 days. Absolute and relative (to body weight and to brain weight) liver weights (LOAEL = 100 mg/kg) were increased compared to controls. No effect on absolute or relative spleen weights were reported. However, trend analyses indicated significant changes in relative spleen weight and spleen/brain ratio in treated mice. Leukocyte and lymphocyte numbers also were increased (LOAEL =100 mg/kg). The percentage of lymphocytes and polymorphonuclear leukocytes also were increased (LOAEL = 50 mg/kg). No changes in serum chemistry parameters (e.g., ALT levels) and bone marrow parameters (e.g., number of cells in the femur) were noted. The number of spleen cells, and percentage of T- and B-cells (LOAELs = 100 and 25 mg/kg, respectively) were altered in treated animals. While the number of spleen cells was decreased 18% at the highest dose tested, the percentage of T-cells and B-cells were increased 75% and 15%, respectively.

Peak IgM and IgG responses (in response to sheep erythrocytes) were observed on days 4 and 5 after immunization, respectively. DAT produced a dose-dependent decrease in IgM (46% at 100 mg/kg) and IgG (56% at 100 mg/kg) AFC responses based on total

spleen activity. DAT exposure also produced a dose-dependent increase in delayed hypersensitivity response to keyhole limpet hemocyanin (2.2-fold increase at 100 mg/kg). Serum CH50 and C3 levels were not significantly affected in mice treated with DAT. The activity of the reticuloendothelial system was increased in the liver (LOAEL = 100 mg/kg), decreased in the spleen (LOAEL = 50 mg/kg) and kidney (LOAEL = 100 mg/kg), and not affected in the lung or thymus of treated mice. Decreased host resistance (LOAEL = 100 mg/kg) to *Streptococcus pneumoniae* and *Listeria monocytogenes*. However host resistance to B16F10 fibrosarcoma and PYB6 melanoma were not affected (Burns et al. 1994).

In vitro data with cells or cell lines

Spleen cells from female B6C3F1 cells treated with 25, 50, or 100 mg/kg DAT for 14 days were evaluated for response to mitogens and DBA/2 spleen cells. DAT exposure did not affect cell

responses to T-cell mitogens PHA and ConA. An increase in responsiveness to LPS was reported in cells obtained from mice treated with 25 or 50 mg/kg, but not those treated with 100 mg/kg.

Spleen cellularity was decreased 20% and 15% at 50 and 100 mg/kg DAT. In response to DBA/2 cells, an enhanced response was observed in responder cells (LOAEL = 100 mg/kg) while no mixed lymphocyte response was noted (Burns et al. 1994).

Peritoneal exudate cells from female B6C3F1 cells treated with 25, 50, or 100 mg/kg DAT for 14 days were allowed to adhere to plastic and the percentage of cells phagocytizing fluorescent Covaspheres or chicken erythrocytes was measured. No significant change in the percentage of phagocytosis was noted at any of the doses (Burns et al. 1994).

Splenic NK cell activity was decreased in cells obtained from mice exposure to DAT for 14 days. A dose-dependent decrease was observed at all effector/target ratios tested (100/1, 50/1, and 25/1). The LOAEL was 50 mg/kg (Burns et al. 1994).

Spleen cell suspensions from female NMRI mice were evaluated to determine whether DAT could modulate luminol-dependent chemiluminescence of phagocytotic cells. Cells were treated with 0.01, 0.1, 1.0, 10, or 100 mg/L DAT. At concentrations greater than 1 mg/L, a dose- dependent decrease in response was observed. When compared to control levels, chemiluminescence was decreased 43%, 90%, and 100% at 1.0, 10, and 100 mg/kg, respectively (Thierfelder and Masihi 1995).

Mode of action information

Based on the combined effects, Burns and colleagues (1994) proposed that DAT affects differentiation and maturation of leukocytes.

5,5-Diphenylhydantoin (DPH) [CASRN 57-41-0]

Human Data

Data from epidemiology studies

In a study of 51 epileptic patients, 20 of whom had not received anticonvulsant treatment for at least two years and 31 of whom had received DPH at 300 mg/24 hours for at least 4 months, the DPH treated group had decreased serum levels of IgA (156 ± 65 mg/100 mL) and IgM (121 ± 43 mg/100 mL) as compared to untreated epileptics (IgA, 179 ± 70 mg/100 mL; IgM, 133 ± 50 mg/100 mL) or control subjects (n= 15; IgA, 223 ± 49 mg/100 mL; IgM, 163 ± 48 mg/100 mL). Serum IgG levels were not statistically significantly different among the groups. The authors concluded that DPH treatment suppresses the normal function of the humoral immune response and that epilepsy may be a contributing factor (Badawy et al. 1991).

Peripheral blood lymphocytes, serum immunoglobulins and complement (C3 and C4) protein concentrations were determined in 20 patients with idiopathic epilepsy who were receiving 200- 300 mg DPH treatment and 30 healthy controls. A significant decrease in T-suppressor cells (28%) and subsequently higher T-helper to T-suppresor lymphocyte ratio (36%) were observed in DPH treated patients. A significant increase in B-lymphocytes (39%) and in serum IgM levels (data in graph) was also observed in DPH treated patients as compared to controls. No significant changes in serum concentrations of IgG, IgA or complement proteins was observed (Basaran et al. 1989).

Peripheral blood lymphocyte subsets, serum immunoglobulins and complement (C3 and C4) protein concentrations were determined in 40 healthy subjects, 30 DPH treated patients (200-300 mg/day), 22 carbamazepine treated patients, and 38 untreated epilepsy patients. Subjects receiving drug therapy had been taking the drug for 3 months up to 20 years. The DPH treated group had decreased IgA (19% and 24%, respectively) and IgG (16% and 14%, respectively) as compared to both healthy subjects and untreated epileptic patients. Significantly lower T- suppressor lymphocyte counts (23% decrease) was observed when compared to healthy controls. Significantly higher T-helper to T-suppressor lymphocyte ratio was observed when compared to healthy subjects and untreated epileptic patients. No significant differences in C3 or C4 protein

levels were observed in DPH treated patients as compared to controls (Basaran et al. 1994).

Serum IgA values were determined in 191 patients taking DPH (dosage not provided). A reduction in serum IgA levels was observed in up to 20% of the patients. Cellular immune status was assessed in the 11% of patients with IgA values lower than two standard deviations below the mean and included: lymphocyte counts, lymphocyte population studies and responses to *in vitro* mitogen stimulation. No significant variations from control values were observed in any of the evaluated endpoints (Burks et al. 1989).

In vitro data with cells or cell lines

No data were located.

Mode of action information

DPH (20 μg/mL) induced IL-1 activity and potentiated LPS-induced IL-1 production in human PMBC and in U-937 cells, a stable monocytic cell line (Modeer et al. 1989).

DPH treatment can lead to a decrease of suppressor T cells and a reversible IgA deficiency in patients with epilepsy. Gingival overgrowth, which often develops in patients taking DPH, is hypothesized to be due to increased production of both IL-6 and IL-8, combined with elevations of basic fibroblast growth factor as observed *in vitro* using human gingival fibroblasts (Beghi and Shorvon 2011; Godhwani and Bahna 2016).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Male Balb/C mice were given DPH at doses of 0, 25, 50 or 100 mg/kg via oral gavage for 7 days. DPH significantly increased cellularity in the spleen (LOAEL = 25 mg/kg), however, both the direct and indirect plaque-forming cells responses following intraperitoneal injection with sheep erythrocytes, were significantly depressed (LOAELs = 25 mg/kg). A significant decrease in the delayed type hypersensitivity in response to sheep erythrocytes was also observed (LOAEL = 25 mg/kg) (Andrade-Mena et al. 1994).

Pregnant Balb/C mice were treated with DPH at doses of 0, 20, 40, and 60 mg/kg via oral gavage on days 9 through 18 of gestation. A dose-related suppression of humoral immune function (measured as the antibody response to type III pneumococcal polysaccharide) was observed in male and female offspring at 25 days, but not at 15 weeks of age (NOAEL = 20 mg/kg). Female offspring of dams treated with 20 or 60 mg/kg DPH had greater antibody levels than controls. No difference was noted in female offspring of dams treated with 40 mg/kg DPH when compared to controls. Cell-mediated immune function (as measured by delayed-type hypersensitivity response to oxazolone) was not affected in offspring of treated dams. Immunosuppressive effects also were greater in offspring born with an open eye defect, also attributed to DPH treatment (Chapman and Roberts 1984).

Female B10.s, B10.d2 and DBA/2 mice were injected with 2 mg DPH and received a single injection of 10 μg TNP-OVA subcutaneously into the right hind footpad. Popliteal

lymph nodes (PLN) were isolated 7 days after injection. DPH increased the number of cells in all three strains (B10.s>B10.d2>DBA/2) (data in graph). IgG1 production to TNP-OVA was increased in all three mouse strains (in B10.d2 about 850-fold; and in B10.s and DBA/2 about 120-fold). DPH treatment did not facilitate immune complex deposition in any of the mouse strains, six days after challenge (Albers et al. 1999).

DPH (administered subcutaneously) produced a significant, dose-dependent response in the PLN assay at 0.5 mg (mean PLN index =1.60 ± 0.18) and 1.0 mg (mean PLN index = 2.79 ± 0.30) as compared to control (mean PLN index = 1.11 ± 0.24) in C3Hf mice. The maximal response occurred at 6-8 days post treatment and returned to normal after 3-4 weeks. The observed response was proposed to be T-lymphocyte dependent since only heterozygous C3H +/nu mice developed PLN enlargement whereas their congenitally athymic C3H nu/nu counterparts did not.

The PLN response to DPH was significantly amplified in thymectomized C57BL/10 mice (PLN index = 6.73 ± 0.83 vs. control PLN index = 2.93 ± 0.53). Proliferation of B lymphocytes was considered a major contributor to the PLN enlargement. A marked increase in IgM and IgG secreting cells was observed following inoculation of BALB/c mice with 1 mg DPH. A maximal increase was observed 10 days after treatment (Gleichmann et al. 1982).

Male C3H/HeN mice were given intraperitoneal injections of DPH (10 mg/mL, once per day) for 28 days and immunized with 100 μg KLH on day 14 and 21. Serum levels of anti-KLH IgG and IgE antibodies were determined on day 28. The KLH-specific IgE response was significantly increased compared to control (data in graph); the IgG response was not changed. Plasma ACTH and corticosterone were significantly higher in DPH-treated mice as compared to controls (data not provided) (Okada et al. 2001).

In vitro data with cells or cell lines

Splenocytes from DPH-treated mice (10 mg/mL for 28 days) immunized with KLH were cultured for 3 days with 50 or 100 μg/mL KLH. No effect on proliferation was noted in splenocytes from DPH-treated mice at either concentration of KLH. Comparatively, splenocytes from control mice immunized with KLH showed a potent proliferative response to stimulation with 50 or 100 μg/mL KLH. T cell function was also impaired in splenocytes from DPH-treated mice, in response to nonspecific mitogens (ConA and LPS) and in response to cross-linking of CD3. The accessory cell function (e.g. macrophages) was also impaired in spleen cells from DPH-treated mice. IL-4 production was significantly enhanced, while IFN-γ and IL-2 production, and NK cell activity were significantly reduced in spleen cells from DPH-treated mice (data in graphs or not provided). IL-1α production was decreased in spleen adherent cells from DPH-treated mice stimulated with *S. aureus*. No effect on IL-6 or IL-12 levels was reported (Okada et al. 2001).

The offspring of female C3H Orleans mice treated with 25 mg/kg diphenylhydantoin 2 times/day throughout gestation, exhibited a reduced thymic cortex and low mitotic activity in the lymphoid population. The reticuloepithelial tissue was enlarged. In the spleen, the white pulp was enlarged due to lymphocyte accumulation. The dams did not

exhibit any changes in the thymus or spleen following treatment (Kohler et al. 1987).

Mode of action information

Heat shock proteins were not induced in the PLNs in female BALB/c mice injected subcutaneously with 2 mg DPH (Albers et al. 1996).

Male ICR mice injected intraperitoneally with 60 mg diphenylhydantoin for 3, 8 and 30 days exhibited elevated levels of serum glucocorticoids and thymic atrophy throughout the experiment (Hirai and Ichikawa 1991).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

In F344/N rats exposed to acetonitrile by inhalation for 13 weeks, gross and histophathologic changes were evaluated in males (800 and 1600 ppm) and females (1600 ppm) that died during the study. Changes reported included thymic atrophy and splenic lymphoid depletion. Decreased absolute and relative thymus weights also were reported in male and female rats (LOAEL =
800 ppm). In F344/N rats exposed to 100, 200, or 400 ppm acetonitrile for 2 years, no immune related effects were reported (National Toxicology Program 1996)

In B6C3F1 mice exposed to acetonitrile by inhalation for 13 weeks, lymphoid depletion and lymphocytolysis in the thymus, spleen and bone marrow was reported in animals that died. A lack of immune effects were reported in mice exposed to acetonitrile for 2 years (NOAEL = 200 ppm) (National Toxicology Program 1996).

Based on a 14-day inhalation study in B6C3F1 mice (doses not provided), acetonitrile was not identified as an immunotoxicant (Luster et al. 1992).

Male Wistar rats were subcutaneously injected with acetonitrile at a dose of 0.8 LD50 (dose not provided). Antibody titer to sheep erythrocytes was decreased by 43%. Additionally, the number of antibody producing cells against sheep erythrocytes and Vi-

Ag (no further information provided in article) were decreased by 52% and 27%, respectively. Thymus T-cell count, percentage of natural cytotoxicity (used as a surrogate for NK cell activity), and antibody- dependent cell cytotoxicity also were significantly decreased after acetonitrile exposure. The percentage decreases were calculated as 31%, 52%, and 41%, respectively (Zabrodskii et al.
2002).

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Benzo(a)pyrene [B(a)P] [CASRN 50-32-8]

Human Data

Data from epidemiology studies

No data were located

In vitro data with cells or cell lines

B(a)P (1 μM) and related metabolites significantly increased IgE-mediated histamine release from human basophils, but did not induce cell death. Additionally, a B(a)P metabolite significantly increased IgE-mediated IL-4 production in human basophils (Kepley et al. 2003). In primary human macrophages, 10 μM B(a)P increased expression of TNF-α and IL-1ß and produced no effect on IFNγ, IL-6, or IL-12 expression (Lecureur et al. 2005). Comparatively, B(a)P did not modulate IL-6 or IL-8 production in BEAS-2B cells at concentrations ranging from 0.1 to 10 μM (Chowdhury et al. 2017).

B(a)P inhibited anti-CD3 antibody stimulation of human lymphocyte proliferation (IC50 =

12.82 μM) (Carfi et al. 2007).

Six breast epithelial cell strains were incubated with 4μM B(a)P for 24 hours. Gene expression studies (using Hu-Gene 133A arrays) showed that signal log ratio (SLR) was altered by ≥1.5 for 5 immune-related genes in at least one of the tested cell strains. Four genes were upregulated, while one was down regulated. Up regulated genes were IL1B, MAL, HTLF, and SECTM1.

CXCL14 gene expression was down-regulated (John et al. 2009).

PBMCs were exposed to ConA and B(a)P and assessed after 3 days. B(a)P dose-dependently decreased DNA synthesis and cell viability in treated cells (LOAELs = 0.01 and 0.1 μM, respectively). The number of cells recovered during the same period also was decreased (LOAEL = 0.01 μM). B(a)P did not affect IL-2 activity or expression of CD25 on small cells or blasts at concentrations up to 1 μM. B(a)P decreased the percentage of blasts that were CD71+ by 13% at 1 μM. Cell cycle analysis indicated that B(a)P increased the percentage of cells in S- phase and decreased the percentage in G0/G1 phase (Mudzinski 1993).

Mode of action information

Calcium mobilization in human T-cells is a proposed mode of action for B(a)P (Krieger et al. 1994). Additionally, Ah receptor activation by B(a)P is proposed to inhibit differentiation of monocytes to macrophages and cell growth of B-cells which may contribute to immunotoxic effects (Allan and Sherr 2005, 2010; van Grevenynghe et al. 2003).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Lactating C3H/HeJ dams were dosed with 0.25, 5.0, or 100 pmol/week B(a)P via oral gavage on PND 1, 8, and 15. Pups (5-weeks old) were treated with OVA via intratracheal instillation every

2 weeks for 6 weeks. B(a)P had no effect on the number of macrophages or lymphocytes in BAL from male or female offspring not treated with OVA. Additionally, no effect was noted on the number of macrophages or lymphocytes in B(a)P-treated offspring that were immunized with OVA (when compared with offspring only treated with OVA). IL-4, IL-5, IL-13, IL-33, and

IFN-γ levels in the BAL were not affected in offspring not treated with OVA. Increased IL-33 and IFN-γ levels were observed in OVA-sensitized female offspring lactationally exposed to 5.0 and 100 pmol/week B(a)P, respectively. Lactational exposure to 0.25 B(a)P increased the total number of mediastinal lymph node cells in males. Lactational 100 pmol/week B(a)P increased numbers of TCRβ+ and CD86+ cells compared with vehicle in non-sensitized male offspring. In non-sensitized female offspring, lactational exposure to 100 pmol/week B(a)P increased numbers of CD11c+ PDCA-1-, CD28+, TCRβ+CD28+, MHC Class II+, and MHC Class II+CD86+ cells.

In OVA-sensitized female offspring, a significant increase in CD11c+PDCA-1+ and CD11c+PDCA-1- cells was observed after exposure to 0.25 and 5.0 pmol/week, respectively (Yanagisawa et al. 2018).

Pregnant C3H/HeB mice were administered 150 mg/kg B(a)P via intraperitoneal injection on GD 11; immune effects were assessed at parturition and again one week after parturition. A significant reduction in newborn CD4+CD8+ (46%), CD4+CD8+Vγ2+ (60%), and CD4+CD8+Vβ2+ (53%) thymocytes were noted. Additionally, CD4+ splenocytes from 1-week- old offspring were significantly reduced (50%) (Rodriguez et al. 1999).

B6C3F1 mice were administered 0.4, 4.0, or 40 mg/kg B(a)P by intratracheal instillation for seven days and immunized with sheep erythrocytes after the last B(a)P exposure. Decreased formation of antigen-specific AFC (by 60%) was observed at 40 mg/kg B(a)P in LALN. When sheep erythrocytes were administered by intraperitoneal injection, an increase in antigen-specific AFC was observed at 40 mg/kg B(a)P in LALN. However, the levels of AFC in the spleen were decreased (Schnizlein et al. 1987).

B6C3F1 mice (3-6 months, 13-16 months, and 23-26 months) were administered 40 mg/kg B(a)P for 8 days by intraperitoneal injection. Mice also were immunized with sheep erythrocytes after day 4 of the B(a)P treatment. Spleens were removed and

splenocytes assessed for formation of AFCs. Decreased formation of AFCs was noted in splenocytes from all three age groups. In two sets of experiments, the observed decreases were 23%-43% in mice ages 3-6 months, 63%- 84% in mice ages 16-18 months, and 93% in mice ages 23-26 months (Lyte and Bick 1985).

B6C3F1 mice were administered 5, 20, or 40 mg/kg B(a)P for 14 days by subcutaneous injection. Spleens were removed and ConA-induced production of IL-2 and IL-3 were assessed. While splenocyte IL-2 production was decreased in a dose dependent manner, no effect on splenocyte IL-3 production was noted. As shown in other studies, B(a)P decreased responses to sheep erythrocytes (>95% inhibition). Addition of exogenous IL-2 to the treated splenocytes, reversed the B(a)P-induced inhibition of responses to sheep erythrocytes (Lyte et al. 1987; Lyte and Bick 1986).

Female B6C3F1 mice were administered 10 subcutaneous injections of B(a)P over a 14-day period at doses of 5, 20, or 40 μg/g. KLH-sensitization did not affect delayed hypersensitivity

responses at the tested doses. Additionally, B(a)P treatment did not induce rejection to DBA mice skin that was grafted onto mice. Proliferative responses to PHA were dose-dependently decreased (LOAEL = 20 μg/g B(a)P). Spontaneous and LPS-induced proliferative responses were increased at 5 μg/g B(a)P and significantly decreased at 40 μg/g B(a)P. MLC responses, and the percentage of spleen cells with T- and B-cell surface markers were not significantly affected at any of the tested doses. Additionally, NK cell activity against YAC- I target cells was not impacted in mice treated with 40 μg/g B(a)P (data not provided). Serum IgG levels were dose-dependently decreased in treated mice (18-24%). A reduction in the number of antibody plaque forming cells to sheep erythrocytes and LPS were noted (LOAELs = 20 and 5 μg/g B(a)P, respectively). B(a)P exposure decreased response to TNP-Ficoll without effects on TNP-LPS response. Host resistance studies showed that B(a)P had no effect on PYB6 tumor incidence or susceptibility to *L. monocytogenes* (Dean et al. 1983).

In vitro data with cells or cell lines

Rat and mouse spleen cells were treated with B(a)P for 24 hours and then LPS or PHA for 48 hours. Then, mitogen stimulation was assessed by 5-bromo-2'-deoxyuridine incorporation. B(a)P inhibited cellular proliferation for both species at similar concentrations (data in graphs). B(a)P also inhibited rat spleen proliferation that was stimulated by ConA (data provided in graph).

B(a)P inhibited anti-CD3 antibody stimulation of mouse lymphocyte proliferation (IC50 > 160 μM) (Carfi et al. 2007).

B(a)P decreased viability of mouse antigen presenting cells (APC) and increased expression of CD86 expression on APC (LOAELs = 0.1 μM). In murine splenocytes, B(a)P decreased cell viability and proliferation (LOAELs = 0.1 and 1.0 μM, respectively). B(a)P did not modulate the expression of T-cell receptors or CD19 at any of the tested concentrations in murine splenocytes (Chowdhury et al. 2017).

B(a)P decreased ConA induced cellular proliferation of mouse splenic T-cells in a dose-dependent manner (LOAEL = 0.1 μg/mL). Inhibition of IL-2, IL-4, and IFN-γ also was observed in ConA-stimulated splenic T-cells (LOAELs = 0.1, 0.2, and 0.1 μg/mL, respectively) (Guan et al. 2017).

B(a)P inhibited spleen cell response to sheep erythrocytes in a concentration dependent manner (LOAEL = 0.01 μM). B(a)P also inhibited one-way mixed lymphocyte response with a maximal inhibition of 19% (Urso et al. 1986). Similar response of murine spleen cell response to sheep erythrocytes was reported by Kawabata and White (1987) (LOAEL = 1 nM) after incubation for 5 days.

Splenocytes from B6C3F1 mice (3-6 months and 23-26 months) were exposed to 1, 10, or

50 μg/mL B(a)P and sheep erythrocytes for 4-5 days. After end of exposure period, the number of AFCs was determined. Dose-dependent decrease in the number of cells was observed in splenocytes from both age groups (data in graphs) (Lyte and Bick 1985).

B(a)P (in PVP-NaCl) dose-dependently increased LPS-induced IL-1 production by peritoneal exudate macrophages isolated from B6C3F1 mice; tested concentrations ranged from 25 to 800

μg/mL. A concurrent decrease in cell viabilities was noted at the same test concentrations. Comparatively, when B(a)P was dissolved in corn oil no effect on IL-1 production or cell viabilities was noted (Lyte and Bick 1986).

Mode of action information

Disruption of T-cell activities has been associated with B(a)P induced immunotoxic effects (Urso et al. 1986). Modulation of mouse splenic T-cell effects was associated with modulation of calcium levels; which was associated with suppression of the NF-□B and NFAT pathways (Guan et al. 2017).

In addition to T-cell effects, modulation of B-cell population or responses, or macrophage functions also have been implicated in B(a)P mode of action (Saxena et al. 2018; Urso et al. 1986). Hardin and colleagues (1992) proposed that B(a)P-induced suppression of B-cell lymphopoiesis was, partially, produced through induction of programmed cell death. Ah-receptor dependent- and/or independent-pathways could produce the observed effects.

Cadmium Chloride [CASRN 10108-64-2]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

Cadmium chloride (10-100 μM) inhibited NK (against K562 cells) and antibody-dependent cellular (against P815 cells) cytotoxicity (ADCC) in peripheral blood lymphocytes in a concentration-dependent manner. The estimated 50% inhibition doses (ID50) for NK and ADCC activities were 50 and 100 μM, respectively. NK and ADCC activities were not significantly affected by changing the effector cell:target cell ratios. Cadmium chloride also inhibited cytotoxic activity against K562 or Daudi cells in activated IL-2 cells (data in graph). Time- course studies showed that a significant decrease in NK and ADCC activities was observed when added at 90 minutes after the start of the experiment (Cifone et al. 1990).

Viability of A549 cells was decreased (44.5% of control) after exposure to 75 μM cadmium chloride. At the same concentration, cadmium chloride increased select cytokine levels (e.g., IFN-γ, IL-3, IL-5, IL-10, IL-15, and IL-16). Comparatively, cadmium chloride decreased TGF- ß3 levels (Odewumi et al. 2016).

Mode of action information

In vitro studies suggest that in peripheral blood lymphocytes, cadmium chloride modulated phosphoinositide hydrolysis induced by a target molecule. This modulation is proposed to lead to inhibited NK activity (Cifone et al. 1990).

Proposed direct action of cadmium on immunocompetent cells stimulates production and release of cytokines, which may produce proinflammatory effects (Marth et al. 2000).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Female BDF1 mice were provided drinking water containing 5, 10, or 50 μg/mL cadmium (as cadmium chloride) for 3 weeks. Antibody response to sheep erythrocytes was decreased in a dose-dependent manner. Splenic plaque-forming cell number decreased by 16% to 28%. A dose- dependent increase in LPS-induced proliferation also was observed (LOAEL = 10 μg/mL). In the absence of a mitogen, cadmium chloride also increased lymphocyte proliferation (LOAEL = 10 μg/mL). No effect was observed when ConA mitogen was used to stimulate proliferation (Blakley 1985).

Female CD1 mice were provided drinking water containing 5, 10, or 50 μg/mL cadmium (as cadmium chloride) for 3 weeks. *In vivo* T-lymphocyte independent (against DNP-Ficoll) and T-

lymphocyte and macrophage independent (against *E. coli*) responses were increased by cadmium exposure (Blakley and Tomar 1986).

Female BDF1 mice were provided drinking water containing 50 μg/mL cadmium (as cadmium chloride) for 3 weeks. Spleen cell suspensions from pooled spleens were separated by adherence techniques and antibody production against sheep erythrocytes was assessed. Suppressed antibody production (26%-34%) was noted in cultures that contained cadmium-exposed T- lymphocytes. Antibody production was similar to controls in cultures that contained cadmium- exposed macrophages (Blakley and Tomar 1986).

Male Sprague-Dawley rats were administered 0.7 or 6 mg/kg cadmium (as cadmium chloride) by oral gavage for 28 days. Splenocyte proliferation was significantly decreased (76% of control) in rats that were administered 6 mg/kg cadmium. Splenocyte IL-2 production also was increased after administration of 6 mg/kg cadmium, when production was normalized with cell number.

No effect was noted on splenocyte IFN-γ production (Wang et al. 2017).

Immunotoxic effects in offspring were noted after exposure to cadmium chloride *in utero* or through milk. In ICR mice administered 2.5 or 5.0 mg/kg cadmium chloride on GD 16, a significant increase in offspring spleen weight was reported (LOAEL = 2.5 mg/kg).

Unstimulated spleen lymphocyte proliferation was significantly increased at both tested doses (1.5- to 2-fold). Additionally, ConA, PHA, and LPS stimulation was increased in treated animals (LOAELs = 5.0, 5.0, and 2.5 mg/kg). No effect on delayed-type hypersensitivity to sheep erythrocytes was reported, but an increase in total Ig and IgM antibody titer was noted at 2.5 mg/kg (Soukupova et al. 1991). In offspring that were exposed to cadmium chloride through maternal milk (dams received 5 ppm or 10 ppb cadmium chloride in water until weaning) decreased spleen weights were observed in females, but not males (data in graphs). The effect was greater in lower dosed females. Effects on organ weight did not persist to adulthood. In adult and juvenile rats, effects on cytotoxic activity of splenic NK-cells was noted (data in graphs). Additionally, cadmium chloride inhibited ConA-induced thymocyte proliferation in both male and female adult rats (Pillet et al. 2005).

Female C57BL/6 mice were exposed (nose-only) to aerosolized cadmium chloride (60-minute exposure to 0.88 mg Cd/m^3) and examined 5-18 days later. Decreased splenic cell viability was observed (data in graph). Significant decreases of proliferative responses to LPS and PHA, and inhibition of IgM secretion in response to sheep erythrocytes were observed. Comparatively, oral chronic exposure (5, 100, or 300 ppm cadmium chloride in water for 12-16 weeks) suppressed IgM response to sheep erythrocytes, without effects on cell viability (Krzystyniak et al. 1987).

In vitro data with cells or cell lines

Splenocytes isolated from male Sprague-Dawley rats were treated with ConA for 24 hours, followed by incubation with 5, 10, or 20 μM cadmium chloride for 4 or 24 hours. After exposure for 4 hours, decreased IL-2 (LOAEL = 5 μM) and IFN-γ (LOAEL = 10 μM) production was observed in the absence of effects on cell proliferation. After exposure for 24 hours, decreased IL-2 (LOAEL = 5 μM) production and cell proliferation (LOAEL = 10 μM) were observed.

When cytokine production after 24-hour exposure was normalized based on cell number,

increased IFN-γ production (LOAEL = 10 μM) was noted. For IL-2 production, a significant decrease was noted at 5 μM and an increase was noted at 20 μM (Wang et al. 2017).

Mode of action information

In RAW264.7 cells, cadmium chloride upregulation of COX-2 and MIP-2 was associated with activation of the phosphatidylinositol 3-kinase/Akt signaling pathway (Huang et al. 2014).

Cadmium chloride also may induce overstimulation of nuclear factors of activated T-cells to activate Jurkat T cells (Colombo et al. 2004).

Dibromoacetic Acid (DBAA) [CASRN 631-61-1]

Human Data

Data from epidemiology studies

No studies were located.

In vitro data with cells or cell lines

In cultured PBMCs collected from healthy, non-smoking volunteers and cultured in DBAA for four hours, DBAA increased the percentage of necrotic human PBMC and decreased PBMC cell size (LOAEL = 5 mM). Increases in the percentage of apoptotic cells and PBMC granulation also was reported (LOAEL = 1 and 5mM, respectively). Caspase-8, -9, and -3 expression were upregulated at 1 and 5 mM. Increased transmembrane mitochondrial potential and levels of reactive oxygen species (ROS) also were noted with DBAA exposure (LOAEL = 1 and 0.1 mM) (Michalowicz et al. 2015).

Mode of action information

DBAA may increase ROS levels and transmembrane mitochondrial potentials (Michalowicz et al. 2015).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

In female F344/N rats exposed to DBAA for 3 months (0-2000 mg/L in drinking water), minimal to mild hematopoietic cell proliferation was noted at the highest dose. A similar effect was not observed in males. While no spleen effects were noted in B6C3F1 mice exposed to DBAA for 3 months (0-2000 mg/L in drinking water), thymus atrophy was reported in males and females (LOAEL = 1000 and 2000 mg/L, respectively) (National Toxicology Program 2007).

In male and female BALB/c mice orally gavaged with 5, 20, or 50 mg/kg DBAA for 28 days altered spleen and thymus weights, and splenic and thymic cellularity were reported. DBAA also inhibited B-cell proliferation (LOAEL = 20 mg/kg). DBAA

increased T-cell mitogenesis (value not provided) at 20 mg/kg. DBAA increased apoptosis in spleen and thymus in a dose-dependent manner (values not provided). Additionally, DBAA exposure altered the expression of apoptosis- related genes in spleens and thymus of treated mice. In the thymus, expression of Fas and TRAF2 were altered (2-2.5 fold). In spleens of treated mice, expression of Fas and TRAF2 were increased 5-fold while bcl-2 expression was decreased 1.5-fold. Increased protein expression of Fas and FasL also were observed in spleen and thymus of treated mice (LOAEL = 5 mg/kg) (Gao et al. 2008).

Table 1. Data from Gao et al. (2008)

Endpoint	0 mg/kgs	5 mg/kg	20 mg/kg	50 mg/kg
Male				
Spleen weight (mg)	80.5 ± 2.7	88.7 ± 3.7	91.2 ± 3.4**	94.0 ± 2.5***

Data are presented as mean ± SEM.

***p < 0.001, **p < 0.01, *p < 0.05, significance assessed by ANOVA when compared with control group (DBA 0 mg/kg).

Increased neuronal expression of immune factors was noted in Sprague-Dawley rats administered 20, 50, or 125 mg/kg DBAA via intragastric injection for 4-weeks. mRNA

expression of Iba-1, NK-□B, IL-6, IL-1ß, and TNF-α were increased in the pre-frontal cortex and hippocampus of treated rats (LOAEL = 50 mg/kg for all brain regions). Protein levels of Iba-1, NK-□B, IL-6, IL-1ß, and TNF-α also were significantly increased in the same brain regions.

Protein expression LOAEL in the pre-frontal cortex for Iba-1, NK-□B, IL-6, IL-1ß, and TNF-α was 50 mg/kg. Protein expression LOAEL In the hippocampus was 100 mg/kg for NK-□B and 50 mg/kg for other evaluated cytokines (Jiang et al. 2017).

Female B6C3F1 mice were given drinking water with 125, 500, or 1000 mg/L for 28 days. A significant decrease in thymus weight was noted at 500 and 1000 mg/L (19%). No effect on absolute or relative spleen weight, or relative thymus weight was reported. A non-dose response decrease (19%) in total spleen cell number and number of CD+CD- T-lymphocytes (13%) was observed at 500 and 125 mg/L, respectively. A significant decrease in absolute (38%) and percent (22%) NK1.1+CD3- cells was noted at 500 mg/L. Significant decreases in absolute and percent splenic macrophages also were observed (LOAEL = 500 and 1000 mg/L, respectively). No effects on absolute or percent Ig+, CD3+, CD4-CD+, or CD4+CD8+ markers were noted. No effects on AFC response or IgM antibody titers in response to exposure to sheep red blood cells were noted. Additionally, no impact on response to allogeneic spleen cell stimulation was noted. A significant decrease in cytotoxicity was only observed after splenocyte NK cell activity was augmented with poly-IC; the effect was only observed at 125 mg/L. Host resistance to *Streptococcus pneumoniae*, *Plasmodoium yoelii*, and B16F10 melanoma tumors was not affect by treatment (Smith et al. 2010).

In vitro data with cells or cell lines

DBAA decreased thymocyte (obtained from BALB/c mice) proliferation at exposure lengths of at least 6 hours. At 6 hours, a significant decrease in proliferation was only observed at 40 μM. Comparatively, at 12, 24, and 48 hour exposure periods a significant decrease in proliferation was observed at 5, 10, 20 and 40 μM. DBAA also decreased IL-2 and IL-4 secretion (LOAEL = 10 and 5 μM, respectively). DBAA also increased late and early apoptosis (LOAEL = 5 and

10 μM), without effects on the percentage of necrotic cells. DBAA induced an increase in the percentage of cells in the G0/G1 phase and decreased the percentage of cells in the S phase. Increased intracellular thymocyte calcium levels (LOAEL = 5μM) and thymocyte Fas and FasL protein levels were reported (LOAELs = 10 μM for both proteins). Additionally, bcl-2 protein level was significantly decreased at all tested concentrations (LOAEL = 5 μM) (Gao et al. 2016).

Peritoneal exudate cells, obtained from B6C3F1 mice treated with 125, 500, or 1000 mg/L DBAA for 28 days, were evaluated for their ability to suppress B16F10 melanoma tumor cell proliferation *in vitro.* Treatment did not affect the ability of macrophages obtained from treated animals to suppress proliferation (Smith et al. 2010).

In Cl.Ly1 + 2/-9 cells, non-adherent cloned T-cell line derived from spleen cells from C57BL/6TL+ mice, DBAA (1-40 μM) decreased cell viability after exposure for 24, 48, or 72 hours (LOAEL = 1 μM). An increase in the mean percentage of early, late and total apoptotic cells also was noted (LOAEL = 5 μM) (Zhou et al. 2018).

Mode of action information

Overall, studies suggest that DBAA produces immunotoxic effects through modulation of T-cell mediated cell immunity. T-cell apoptosis, through extrinsic and intrinsic pathways, are proposed to play a role in the mode of action. Apoptosis may occur through a variety of pathways including modulation of transmembrane potential, the Fas/FasL pathway, modulation of intracellular calcium, and cell cycle arrest (Gao et al. 2008; Gao et al. 2016).

Dibutyl phthalate (DBP) [CASRN 84-74-2]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

DBP significantly decreased phagocytotic capacity of differentiated THP-1 cells at all tested concentrations (LOAEL = 0.001μM). DBP also increased TNF-α secretion (LOAEL = 0.1 μM). Comparatively, DBP had no effect on IL-1ß or IL-8 secretion from differentiated THP-1 cells (NOAEL = 0.001 μM) (Couleau et al. 2015).

High-density microarray studies were conducted using normal human mammary epithelial cell strains obtained from discarded tissues; cells were treated with 1 μM DBP for 10 hours. Gene expression of 29 genes were increased in all four isolated cell strains. Gene expression of 28 genes were decreased in all four isolated cell strains including genes involved in the immune response (TNF-α-induced protein 3; values not provided) (Gwinn et al. 2007).

DBP (tested at 0.1 and 100 μM) increased IL-6, CXCL8, and IL-10 secretion from monocytes/macrophages, isolated from blood of healthy individuals. The cells were, stimulated with *E. coli* lipopolysaccharide (LPS) for 1 hour. Comparatively, DBP did not affect IL-1ß and decreased TNF-α secretion from the cells. For all affected cytokines the LOAEL was 100 μM. For phytohemagglutinin-P (PHA-P) stimulated T cells, DBP decreased IL-2, IL-4, TNF-α and IFN-γ secretion (LOAEL for all cytokines = 100 μM). No effect on IL-6 or IL-10 secretion was observed in the PHA-P stimulated T cells treated with DBP. Metabolism studies indicated that DBP was metabolized to monobutyl phthalate *in vitro*. Additionally, secretion patterns of monobutyl phthalate was similar to those observed for DBP (Hansen et al. 2015).

DBP increased IL-1ß gene expression (as assessed by RT-PCR) in human corneal endothelial cell line B4G12 at all tested concentrations (LOAEL = 1 μM). IL-8 gene expression was increased at 1 and 10 μM (values not provided). IL-ß, IL-8, and IL-6 secretion from cells also was increased. IL-6 and IL-8 LOAEL values were 10 and 5 μM,

respectively. Significant IL-1ß secretion was only observed at 1 µM. [Note: The authors note that secretion for IL-1ß and IL-6 was low and quantification was approximate] (Kruger et al. 2012).

In THP-1 cells, DBP did not induce release of IL-18 (doses tested not provided) or IL-8 (NOAEL = 250 µM), or expression of CD86 (NOAEL = 250 µM). However, DBP did induce IL-8 mRNA expression at 500 µM after exposure for 3 hours (values not provided in paper) (Lourenco et al. 2015).

In HepG2 and L02 (normal human liver) cell lines, DBP (10 µM and 25 µM, respectively) significantly increased levels of mature caspase-1, IL-1ß, and nucleotide oligomerization domain (NOD) like receptor family, pyrin domain containing 3 (NLRP3) (values not provided). KN-62,

a P2X7 receptor inhibitor, attenuated DBP-induced effects on caspase-1, IL-1ß, and NLRP3 (Ni et al. 2016).

In primary human keratinocytes cultured on an amorphous pseudodermis, DBP increased TSLP (thymic stromal lymphopoietin) mRNA expression (Schuepbach-Mallepell et al. 2013).

Mode of action information

Studies suggest that innate and adaptive immune system is impacted by DBP exposure (Hansen et al. 2015). DBP is proposed to be metabolized to the monoester *in vitro*. This compound then is proposed to modulate cytokine secretion from both monocytes/macrophages and T cells.

The results from Couleau and colleagues (2015) suggest that some effects may occur through activation of the endocrine pathway. DBP also may regulate gene and protein expression of a variety of immune factors (e.g., cytokines) without impacting cell viability.

Immunomodulation by DBP also may occur through receptor-mediated effects on the inflammasome.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

DBP did not increase proliferative responses in lymph nodes of BALB/c mice at concentrations up to 20% (v/v in acetone; dermal route of exposure). Additionally, 10% DBP did not increase dendritic cell accumulation in draining lymph nodes (Dearman et al. 1996).

Wistar rats were fed a diet containing 0.5% or 5% DBP for 34-36 days. While no effect on absolute spleen weight was reported, a significant increase (1.8-fold) in relative spleen weight was reported at 5% DBP (Murakami et al. 1986).

Female BALB/cJ mice were subcutaneously exposed to ovalbumin (antigen) and 2-2000 µg/mL DBP. After the primary immunization, one or two booster shots were given to the mice. No effects on the IgG1 or IgE serum levels after either one or two booster shots were noted. A dose- dependent effect was observed on IgG1 serum levels;

maximum responses were observed at 200 μg/ml (value not provided). No effect was noted on IgE serum levels (data not provided) (Larsen et al. 2002).

Thymic stromal lymphopoietin (TSLP) mRNA expression was significantly increased in BALB/c mouse ears 24 hours after exposure to DBP (in acetone, 1:1) (values not provided). An increase in TSLP protein levels was also measured at 24 hours (values not provided) (Larson et al. 2010; Schuepbach-Mallepell et al. 2013). DBP-induced induction of TSLP was strain dependent (BALB/c was more sensitive than C57Bl/6 mice). DBP also produced effects on TSLP in IL-1 receptor or apoptosis-associated speck-like protein containing a caspase recruitment domain deficient mice (Schuepbach-Mallepell et al. 2013).

In vitro data with cells or cell lines

DBP was cytotoxic to murine peritoneal exudate macrophages (PEM) after exposure to 50 or 100 μM for 24 hours. Annexin V and PI double stained cells (markers of apoptosis) were significantly increased after treatment with 100 μM DBP for 24 hours. Additionally, using trypan blue exclusion, a significant decrease in viable cells was reported after DBP exposure (LOAEL = 50 μM). Using two-color flow cytometry, DBP was shown to decrease expression of CD80, CD36, and major histocompatibility-II molecules on F4/80+ macrophages at 1 and 10 μM. Cytokine expression (IL-1ß, IL-6, IL-12, and TNF-α) also were decreased at the same concentrations. Phagocytotic capacity of PEM to apoptotic thymocytes and *E. coli* was decreased after exposure to DBP when compared to controls (LOAEL = 1 μM). DBP exposure also decreased PEM immunogenicity to allogenic T cells (LOAEL = 1 μM) (Li et al. 2013).

DBP decreased cell viability of RAW 264.7 macrophages (LOAEL = 100 μM for 60 minutes) but did not increase cellular apoptosis (NOAEL = 1 mM for 60 minutes) (Naarala and Korpi 2009).

In RBL-2H3 mast cells sensitized with anti-dinitrophenyl monoclonal IgE, DBP potentiated ß- hexosaminidase activity, which was used as a measurement of degranulation (LOAEL = 50 μM for 10 minutes). DBP did not induce degranulation in the cells that were not sensitized (NOAEL
= 500 μM for 10 minutes) (Nakamura et al. 2002).

In PAM212 keratinocytes, 1% DBP increased relative expression of TSLP; maximal effect (values not provided) was observed at 36 hours post treatment (Larson et al. 2010). DBP-induced TSLP expression was associated with epidermal mouse skin and human abdominal skin transplanted on mice (Schuepbach-Mallepell et al. 2013).

Mode of action information

In vivo rodent studies suggest that DBP impacts the Th2 response. Inflammasome activation by DBP impacts TSLP expression and Th2 response.

In vitro studies suggest that while high doses of DBP induced macrophage apoptosis, moderate doses induced protein expression and production of cytokines. DBP also impacted the antigen- presenting capacity of macrophages.

Dichloroacetic Acid (DCAA) [CASRN 79-43-6]

Human Data

Data from epidemiology studies

No studies were identified.

In vitro data with cells or cell lines

A single study suggested that DCAA may produce immunosuppressive effects. Using a two-way mixed lymphocyte reaction, DCAA (LOAEL = 0.33 mM; lowest dose tested) increased IL-10 production and FOX P3 expression 11.4- and 4.5-fold, respectively (Eleftheriadis et al. 2013).

DCAA (3.0 mM and 0.5 mM, respectively) increased IL-2 production after incubation for 16 hours and expression of the T-cell activation marker CD25 in Jurkat cells. Comparatively, no effect on CD69 expression (0.5 and 3.0 mM) was noted. IL-2 and IFN-γ mRNA expression was significantly increased after DCAA treatment (3.0 and 0.5 mM, respectively) (Pan et al. 2015).

DCAA (N/LOAEL = 0.1/1.0 mM) induced statistically significant increases in necrosis in PBMC, as shown by a decrease in PBMC cell size combined with an increase in cellular granulation. Statistically significant increases in the percentage of apoptotic cells were observed at similar concentrations of DCAA (N/LOAEL = 1.0/2.0 mM) (Michalowicz et al. 2015).

Mode of action information

T-cell activation was one proposed mode of action for DCAA. Increased IL-10 production, combined with increased FOX P3 expression, is proposed to increase regulatory T-cell differentiation which may lead to increased IL-10 production. Additionally, DCAA increased expression of T-cell activation markers in Jurkat cells.

Apoptosis was proposed be associated with a variety of mechanisms including ROS generation, alterations in mitochondrial transmembrane potential, and activation of caspase activity.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

In a 90-day drinking water study (0, 50, 500 and 5000 ppm (w/v) DCAA) with male Sprague- Dawley rats, a significant increase in relative spleen weight was noted at 5000 ppm (0.25% vs. 0.21%). No consistent effects on T cell-dependent anti-keyhole limpet hemocyanin IgG antibody production (measured by ELISA), delayed hypersensitivity to bovine serum albumin, NK cell cytotoxicity, or production of peritoneal macrophage-derived PGE2 or spleen lymphocyte- derived IL-2 were detected at tested doses (data not shown in paper) (Exon et al. 1986; Mather et al. 1990).

In autoimmune-prone MRL +/+ female mice, 0.5 mg/mL DCAA (provided *ad libitum* in drinking water for 12 weeks) significantly increased serum IgG (32%) and IgM (30%) levels. DCAA significantly decreased IL-10 (34%) and KC chemokine (31%) in liver extracts from

MRL +/+ mice. Comparatively, a significant increase in serum IgG3 levels (27%) was observed in wild-type B6C3F1 after DCAA exposure. In liver extracts from treated B6C3F1 mice, DCAA significantly increased IL-4 (400%), IL-5 (33%), IL-6 (53%), IL-10 (25%), IL-12 (32%), KC

chemokine (18%), GM-CSF (42%), G-CSF (56%), and IFN-γ (45%) compared to controls. Compared to isolated MRL +/+ splenic lymphocytes from controls, DCAA decreased IL-4 and IL-10 secretion in MRL+/+ treated mice. DCAA decreased IL-4 and increased IFN-γ secretion from splenic lymphocytes from treated B6C3F1 mice when compared to controls (values not provided). DCAA also significantly decreased IL-4 and IL-2 secretion and significantly increased IL-5, IFN-γ, and GM-CSF secretion from B6C3F1 isolated splenic lymphocytes when compared to secretion from MRL +/+ isolated splenic lymphocytes from treated animals (values not provided) (Cai et al. 2007).

In vitro data with cells or cell lines

No studies were identified.

Mode of action information

DCAA-induced increase of p53 accumulation has been proposed to lead to increased formation of cells in G2-M phase (Staneviciute et al. 2016).

Diethylstilbestrol (DES) [CASRN 56-53-1]

Human Data

Data from epidemiology studies

Male and female offspring of pregnant women given DES doses from the seventh week to 34th week of pregnancy, were interviewed about immune-related health problems. A total of 549 DES-exposed offspring and 487 placebo-exposed offspring participated in the study. Rates of allergy-related health problems (e.g., asthma, drug allergy, hives) were similar between DES- and placebo-offspring. Infection (e.g., shingles, flu) and autoimmune disease (e.g., diabetes, rheumatoid arthritis) also were similar between the two groups (Baird et al. 1996).

The frequency of any autoimmune disease in women exposed to DES *in utero* (n = 1711) was higher than the frequency observed in control women. The overall frequency was 28.6 per 1000 women compared to 16.3 per 1000 women. Hashimoto's thyroiditis was significantly more prevalent (relative prevalence = 5.4) in exposed women compared to controls (Noller et al.

1988).

Increased incidence of asthma, arthritis, and diabetes mellitus was reported in sons and daughters exposed to DES *in utero* when compared to unexposed individuals. Additionally, the number of respiratory tract conditions (e.g., colds) was increased in the exposed population vs. the unexposed population (Wingard and Turiel 1988).

In vitro data with cells or cell lines

Lymphocyte NK activity (assessed using chromium release from K562 cells) from 12 patients exposed to DES *in utero* was greater than observed from controls; however, effects were not significant. No effects on adherent cells were noted (Ford et al. 1983). Comparatively, DES dose-dependently inhibited lysis of K562 cells in PBMCs obtained from 12 patients. At the highest concentration tested (100 μM), an 82% reduction in activity was observed compared to control samples (Ablin et al. 1988b, 1988a)

Responses to 0.125 μg/mL PHA (as measured by uptake of radiolabeled thymidine) was significantly greater in peripheral blood monocytes from women exposed to DES *in*

utero compared to controls (88.6×10^3 vs. 44.0×10^3 cpm; $p < 0.002$). Maximal blastogenic response to PHA in lymphocytes from DES-exposed women was observed at 0.125 μg/mL while it was observed at 0.25-0.50 μg/mL in controls (Ways et al. 1987).

Mode of action information

DES inhibits the lytic activity of human NK cells (Kalland and Campbell 1984).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

C57BL/6 dams were orally administered 48 μg/kg DES from GD 14-16 and then sacrificed on GD 18. Fetal thymic weight and cellularity were significantly decreased (44% and 51%, respectively) in treated animals. Relative fetal thymic weight was decreased 28% when compared to controls. The percentage of thymocytes in the CD4-8- and CD4-8+ populations were increased 87% and 138%, respectively. Comparatively, CD4+8+ thymocyte population was decreased 12%. Increased apoptosis of CD4+8+, CD4-8+, and CD4-8- thymocytes also was observed (Besteman et al. 2005).

Male and female CD-1 mice were subcutaneously injected with 5, 15, or 30 μg/kg DES, four times on alternate days. Relative thymic weight (LOAEL = 30 μg/kg) was decreased, and absolute and relative splenic weights (LOAELs = 15 μg/kg) were increased in female mice. A similar effect in male mice was not observed. Relative expression of thymocyte populations (e.g., CD4-8-) were not affected in males or females. However, an increase in the number of total apoptotic and decrease in the number of live CD4+8+ and CD4+8- thymocytes was observed in male and female mice. Additionally, an increase in the number of total apoptotic and decrease in the number of live CD4-8- cells were observed in females. Increased proliferative response to ConA, LPS, or PMA was observed in splenic lymphocytes isolated from female mice treated with 5 μg/kg DES. At higher doses, a trend for decreased proliferation was observed in female splenic lymphocytes. Proliferative responses by splenic lymphocytes were only modulated in response to ConA at 15 μg/kg DES (Calemine et al. 2002).

Female mice (strain not provided) were administered (route not provided) 0.2, 2.0, or 8.0 mg/kg DES for 5 days. Antibody response to sheep erythrocytes and LPS were decreased 15% to 45% (LOAELs = 2.0 mg/kg). Delayed hypersensitivity response to keyhole lymphet hemocyanin was similar to controls when mice were exposed to DES before sensitization. However, when mice were exposed to DES after sensitization and before challenge a decrease in response was observed (LOAEL = 2 mg/kg). The percentage of splenic T lymphocytes was decreased 25% at the highest dose tested. No effect on the percentage of splenic B lymphocytes was observed.

Splenic lymphoproliferative response to PHA and ConA were decreased (>30%) at all

tested doses. Responses to *Staphylococcus* enterotoxin A were increased at 0.2 mg/kg and decreased at higher doses, while responses to LPS were increased at 0.2 and 2.0 mg/kg and decreased at 8.0 mg/kg. MLC responses also were decreased (LOAEL = 2 mg/kg). Suppressor cell activity was decreased after exposure to 8 mg/kg DES (Luster et al. 1980).

Differential effects on the immune system were observed in female NMRI mice depending on the time of DES exposure. Thymus weights were increased in 56-day-old mice that were subcutaneously injected with 5 µg from PND 1-5, 6-10, or 30-34 (1.2- to 1.4-fold).

Comparatively, thymus weight was decreased in mice subcutaneously injected with DES from PND 48-52 (29%). A dose-related effect on thymus weight was observed in mice treated from PND 1-5; no effects on absolute or relative spleen weight were noted. Differences in thymus weight also were noted depending on when the mice were killed after treatment. Four days after treatment, thymus weights were decreased in all test groups. However, 4 to 8 weeks after

treatment showed an increase in thymus weight in mice treated on PND 1-5 and weights similar to controls in other treatment groups. DES treatment on PND 1-5 also reduced the number of cells in S-phase in the thymus (Forsberg 1996).

C57BL/6 mice were treated with DES once *in utero* and/or once at 12-16 months of age via subcutaneous injection. Increased secretion of IFNγ was observed in splenic lymphocytes obtained from mice exposed to DES *in utero* and as adults. Increased IFNγ also was observed when splenocytes were stimulated with anti-CD3 antibodies. This increase was not observed in other treatment conditions (data in graphs). An increase in IFNγ production also was observed in T-cells from mice exposed to DES *in utero* and as adults (Karpuzoglu-Sahin et al. 2001).

In vitro data with cells or cell lines

DES stimulated IL-1 production from peritoneal exudate macrophages at concentrations ranging from 0.01 to 1 μM; the maximal response was observed at 0.1 μM. DES (0.1 μM) also significantly increased production of IL-6 (1.7-fold), IL-12 (9.5-fold) TNF-α (3.1-fold), and macrophage chemotactic protein 1 (7.2-fold), and surface expression of CD86 (1.6-fold). DES also increased proliferative responses (8.6-fold) and IL-2 production (5.6-fold) observed when macrophages were incubated with purified T cells. Anti-MHC-II, -CD-80, and -CD86 blocked effects produced by DES (Yamashita et al. 2005).

DES increased IgE levels in male BALB/c mouse splenocytes at concentrations greater than 1 μM. Comparatively, DES had no effect on IgM, IgG, or IgA levels at concentrations up to 1 mM (Han et al. 2002).

Mode of action information

DES-induced thymic atrophy was proposed to be due, in part, to estrogen-related thymocyte apoptosis (Besteman et al. 2005; Fenaux et al. 2004). Brown and colleagues suggested that DES exposure upregulates TNF family members, which leads to altered T-cell development. This alteration was suggested to lead to thymic atrophy (Brown et al. 2006). Direct effects on T lymphocytes also may occur (Luster et al. 1980).

In mice, DES exposure was associated with down-regulation of gene expression in the TCR complex, and the TCR and CD28 signaling pathways. Genes in the B-cell receptor

signaling pathway, antigen presentation, and dendritic cell pathways also was altered by DES exposure. It was proposed that DES dysregulation of T-cell development plays a role in thymus effects (Frawley et al. 2011). Alterations of microRNA expression also has been proposed as playing a role in the immunotoxic effects produced by DES (Singh et al. 2015).

Additional proposed modes of action on the immune system include effects on adherent suppressor cells, modulation of NK activity by interfering with bone marrow lymphoid precursors, and modulation of the mononuclear phagocyte system (Dean et al. 1986; Forsberg 1984; Kalland 1984; Luster et al. 1980).

Ethylene Dibromide (EDB) [CASRN 106-93-4]

Human Data

Data from epidemiology studies

The prevalence of adult-onset asthma, in relation to lifetime pesticide use, were assessed using data from the Agricultural Health Study (19,704 male farmers). Adult-onset asthma was reported in 441 individuals; 127 classified as allergic and 314 classified as non-allergic. EDB exposure was positively associated with allergic asthma (OR: 2.07 [1.02-4.20]) (Hoppin et al. 2009).

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Female B6C3F1 mice were intragastrically treated with 100, 125, 160, or 200 mg/kg EDB for 14 days. Relative thymus and spleen weights were decreased in a dose-related manner (LOAEL = 200 mg/kg). Comparatively, relative liver and kidney weights were increased at higher doses (LOAEL = 125 and 160 mg/kg, respectively). Significant increases in white blood cells (LOAEL
= 200 mg/kg) and neutrophils (LOAEL = 160 mg/kg) were noted. Host resistance to influenza A2, *Listeria monocytogenes*, and herpes simplex virus types 1 and 2 was not significantly affected by EDB exposure. The total number of resident peritoneal exudate cells were significantly increased in EDB-treated mice (LOAEL = 160 mg/kg). However, the percentage of cell types present in the exudates were similar to those observed in control exudates (macrophages: 53%; lymphocytes: 47%). Phagocytosis of radiolabeled chicken red blood cells was increased in peritoneal macrophages obtained

from EDB-treated mice (187% of control; LOAEL = 125 mg/kg). Splenic NK cell activity was evaluated in animals treated with 100, 125, or 160 mg/kg; a significant decrease in activity was observed at 160 mg/kg. The number of viable cells in the spleen decreased at 125, 160, and 200 mg/kg (not significant), while a significant increase in the number of anti-SE PFC/10^6 viable spleen cells was significantly increased at 160 mg/kg. Splenic lymphocyte responses to allogenic spleen cells, PHA and ConA, but not LPS, were significantly decreased at 125 and 160 mg/kg (Ratajczak et al. 1994).

Female B6C3F1 were intragastrically treated with 31.25, 62.5, or 125 mg/kg EDB for 5 days per week for 12 weeks. No effect on white blood cell numbers, or the percentage of neutrophils or lymphocytes were noted at the doses tested. Splenic lymphocyte responses to PHA and LPS were significantly decreased at the highest dose tested (data not provided) (Ratajczak et al.

1995).

Relative spleen weights were not significantly affected in male Sprague-Dawley rats inhalationally exposed to EDB 7 hours per day, 5 days per week, for 30 days. However, relative liver weights were increased at the highest dose tested (LOAEL = 455 ppm) (Igwe et al. 1986).

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Glycidol [CASRN 556-52-5]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Of 10 F344/N female rats that received 400 mg/kg glycidol for 13-weeks (via gavage), lymphoid necrosis of the thymus was observed in nine (Irwin et al. 1996; National Toxicology Program 1990). Enlarged spleen were observed in haploinsufficient $p16^{Ink4a}/p19^{Arf}$ male mice treated with 200 mg/kg glycidol for 40 weeks via gavage (National Toxicology Program 2007).

Increased splenic fibrosis incidence was reported in male and female F344/N rats gavaged with

37.5 and 75 mg/kg glycidol for 2 years. In males, splenic fibrosis incidences were 26% in controls, 68% in rats treated with 37.5 mg/kg, and 56% in rats treated with 75 mg/kg. In females, splenic fibrosis incidences were 6%, 29%, and 40% for control, 37.5 mg/kg rats and 75 mg/kg rats, respectively (National Toxicology Program 1990).

In female B6C3F1 mice administered glycidol via gastric intubation (25, 125, and 250 mg/kg) for 14 days, no effect on spleen or thymus weights, or leukocyte or lymphocytes counts were reported. To assess AFC response, treated mice were intravenously exposed to sheep erythrocytes on day 11 and spleen IgM AFC response was measured 4 days later. At the highest treatment dose, there was a 31% reduction in specific

activity. When expressed as total spleen activity, significant decreases were noted at 125 and 250 mg/kg (29% and 41%, respectively).

Splenic T-cell proliferation, in response to 10 μg/mL ConA was significantly decreased (16% and 26%, respectively) in splenocytes obtained from mice treated with 125 and 250 mg/kg glycidol. B-cell proliferation, in response to Il-4 or Il-4 and goat anti-mouse IgM F(ab')2, was only decreased in splenocytes obtained from mice treated with 125 mg/kg glycidol (13% and 16%, respectively). Comparatively, proliferation in response to goat anti-mouse IgM F(ab')2 was decreased in splenocytes from mice treated with 125 and 250 mg/kg glycidol (30-32%). While glycidol had no effect on lymphocyte blastogenesis (as assessed by splenocyte proliferative response) alone, in the presence of allogenic DBA/2 spleen cells a 25% decrease in response was noted at the middle dose only. NK cell activity in spleens was decreased at two ratios of effector:target ratios (100:1 and 50:1); the LOAELs at both ratios were 125 and 250 mg/kg, respectively. Using flow cytometry, the number and percent of B lymphocytes, T-lymphocytes,

$CD4^+CD8^-$, $CD4^-CD8^+$, and $CD4^-CD8^-$ cells from spleens isolated from treated mice were quantified. The total number of spleen cells, B lymphocytes, and $CD4^+CD8^-$ were significantly decreased at 250 mg/kg. The LOAEL also was 250 mg/kg when the percent values of B and T lymphocytes were assessed (Guo et al. 2000).

In vitro data with cells or cell lines

To further assess the effect of glycidol on the immune function, Guo and colleagues (2000) conducted a set of *ex vivo* assays. Glycidol inhibited cytotoxic T cell activity in spleens obtained from mice administered glycidol via gastric intubation (25, 125, and 250 mg/kg) for 14 days.

Splenocytes were sensitized with mitomycin C-exposed P815 mastocytoma cells, and co- cultured with labeled P815 cells at a variety of effector:target ratios. At an effector:target ratio of 25:1 and 0.75:1, glycidol inhibited CTL activity at a 25 mg/kg when compared to vehicle (53.8 vs. 31.5, and 8.8 vs. 2.1, respectively). At a ratio of 12.5:1, CTL activity was decreased significantly (39%) in spleens from mice treated with 125 mg/kg glycidol (Guo et al. 2000).

Resident macrophage activity (in the presence of macrophage stimulators) was assessed in mice treated with glycidol via gastric intubation (25, 125, and 250 mg/kg) for 14 days. Increased cytotoxicity was only observed after treatment with 25 mg/kg glycidol in the presence or absence of macrophage stimulators (1.7- to 2.5-fold increase) (Guo et al. 2000).

Host resistance to B16F10 melanoma cells, *Listeria monocytogenes* and *Streptococcus pneumoniae* were assessed in mice treated with glycidol via gastric intubation (25, 125, and 250 mg/kg) for 14 days. Glycidol increased pulmonary tumor formation in mice treated with B16F10 melanoma cells (LOAEL = 125 mg/kg). No effect on host resistance was noted at the three challenge levels of *Listera monocytogenes* (1, 2, or 4×10^4 CFU/mouse). At the challenge

level 5.52×10^7 CFU *Streptococcus phenumoniae*/mouse, increased host resistance was observed in the 250-mg/kg glycidol treated mice (Guo et al. 2000).

Mode of action information

Studies suggest that glycidol modulates B-cell function, and NK cell and macrophage activities (Guo et al. 2000).

Hydrocortisone (HC) [CASRN 50-23-7]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

The effect of HC on IL-4-induced IgE production was measured in PBMCs isolated from healthy volunteers. HC induced an ~20 fold increase in IgE production at a LOEL of 1×10^{-7} M. HC did not have any effect on IgE production in the absence of IL-4 (data not shown) (Nüsslein et al.
1994).

Blood samples from healthy adults were pre-treated with 30 μg/dL HC (identified as cortisol); INF production was then stimulated with Newcastle disease virus. HC decreased IFN-α response by 50-60% (data in graph) (Reissland and Wandinger 1999).

Mode of action information

Keh and colleagues (2003) reported that in septic shock patients, HC attenuated inflammatory and anti-inflammatory responses without inducing immunosuppression.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Swiss inbred mice were intraperitoneally injected with 0, 1.5, 5 or 15 mg/kg of HC. Forty-eight hours later, there was a significant decrease in thymus weight at 15 mg/kg (data in graph). To test the effect of HC on delayed hypersensitivity, mice were immunized with sheep erythrocytes in FCA, challenged in the footpad on day 5, and treated simultaneously with increasing amounts of HC. The mice received another injection of HC two hours before measuring 24-hour footpad swelling. 5 and 15 mg/kg HC suppressed footpad swelling (data in graph). Glucocorticoid- induced leukopenia and monocytopenia was evaluated in mice 2.5 hours after intravenous injection with

HC. The numbers of circulating nucleated and monocytic cells was maximally decreased at the lowest dose tested (1.5 mg/kg), with the number of both cell types increasing with increasing dose (data in graph). A plasma transfer study found that 2.5 hours after transfer, the plasma of HC treated mice raised the number of nucleated cells in saline treated acceptor mice by 46%. To evaluate feedback-inhibition, mice were injected (route not specified) with 5 mg/kg HC for four days and examined 7 or 11 days (data not shown) after the last injection. At day 7, HC had no effect on delayed hypersensitivity, serum corticosterone, or numbers of circulating nucleated and monocytic cells (data in graphs) (Van Dijk et al. 1979).

In a trio of studies by El Fouhil and colleagues (El Fouhil et al. 1993a, 1993b; El Fouhil and Turkall 1993), immunologically immature rats were treated subcutaneously with 400 mg/M^2/day HC, administered on alternate days from PND 7 to PND 19. At two days after the last treatment (PND 21), thymus and spleen weights were decreased (71 and 28%) compared to vehicle control,

but at PND 42 organ weights were increased (18 and 7%). Leucocytosis was increased in PND 21 and 42 rats (12 and 24%), with a decrease in IgM concentration in serum (45 and 15%). At PND 21 there was a 46% decrease in the percentage of lymphocytes, which resolved by PND 42 (El Fouhil and Turkall 1993). On PND 21, splenic white pulp was largely depleted of small lymphocytes. There were no distinct periartiolar lymphoid sheaths and no primary follicles. The number of T cells surrounding the central arteriole was decreased (data not shown). By PND 42, the pulp appeared normal (El Fouhil et al. 1993a). On PND 21, the outer cortex of mesenteric lymph nodes was found to be depleted of small lymphocytes and primary follicles, and neither cortical expansion nor capsular indentations were detected. There was a marked depletion of B lymphocytes, which were more or less discrete and did not aggregate to form follicles. There was no apparent change in T lymphocytes. On PND 42, the lymph nodes were comparable between HC treated and control rats (El Fouhil et al. 1993b).

HC (1.5 mg intraperitoneally administered) decreased formation of splenic anti-sheep erythrocyte (4×10^7 sheep erythrocytes) PFC in female BALB/c mice (data in graph). HC did not affect IgM-PFC or IgG-PFC response or serum antibody titers (data in graphs) (Jokay et al.
1980).

In vitro data with cells or cell lines

Indomethacin [CASRN 53-86-1]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

Heparinized whole blood, from healthy adult volunteers, was incubated with 1 to 50 μM indomethacin for 1 hour prior to stimulation with LPS. A significant increase in IL-6 expression was only noted at 50 μM indomethacin (129.7%). Comparatively, a dose-dependent increase in TNF-α was observed, and at 50 μM the number of TNF-α positive cells had doubled (204.7%) (Hartel et al. 2004).

Human PBMC were treated with 1, 10 or 100 μM indomethacin. At all tested doses, indomethacin decreased LPS-induced PGE2 synthesis to near 0%; the calculated IC50 was

0.039 μM (data in graph). Indomethacin also decreased IgG and IgM production (data in graph) at all doses tested. Indomethacin up-regulated IL-2 production and down-regulated IL-6 production in treated PBMC (data not shown). Increased PHA-, anti-CD3, and IL-2-induced lymphocyte proliferation was reported after indomethacin exposure. NK activity (against K562 target cells) was increased at 1 (1.5-fold) and 10 (1.5-fold) μM. A significant effect on LAK cell activity was not observed at 50 μM. Co-incubation of PBMCs with IL-2 and indomethacin caused an increase in IFN-γ production by LAK cells at 1, 10 or 100 μM (data not shown) (Tanaka et al. 1998).

Indomethacin (5.6 μM) increased proliferation of PHA- and ConA-stimulated lymphocytes (in mononuclear cell cultures) (data in graph). The effect was only observed at suboptimal concentrations of PHA and ConA. The observed increased proliferation was lost at optimal and supraoptimal concentrations. Additional testing showed indomethacin increased PHA-stimulated lymphocyte proliferation in a dose-dependent manner (LOEL = 0.04 μM). Removal of adherent cells from the culture negated the stimulatory effect produced by indomethacin. Indomethacin did not affect cell viability, but increased incorporation of tritiated thymidine in a dose- dependent

manner (Jawad and Rogers 1984).

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Female C57BL/6 mice were orally administered 5 mg/kg indomethacin for 4 days. Animals were then immunized with sheep erythrocytes and then serum hemagglutination and AFC titers were assessed 4 and 8 days, or 6 days later, respectively. Indomethacin decreased both titers by approximately 40% (data in graphs). Indomethacin also decreased ConA- and LPS-induced

stimulation of lymphocyte proliferation (data in graphs). Incubation of indomethacin (3 μM) with LPS-stimulated lymphocytes isolated from indomethacin-treated mice decreased proliferation (Barasoain et al. 1980).

Female B6C3F1 mice were subcutaneously injected with 1, 2, or 4 mg/kg indomethacin for 6 days. Studies were conducted on mice 3 days after final treatment. No effect on thymus weight was reported, while 4 mg/kg indomethacin caused a 38% increase in spleen weight. A

dose-dependent increase in splenic lymphocyte proliferation (10%-80%) was observed in non- stimulated cultures. Increased proliferation was observed in LPS-stimulated cultures from mice treated with 1 or 2 mg/kg indomethacin (13% and 22%, respectively), while a decrease was observed at the highest indomethacin dose. Comparatively, decreased proliferation was observed in PHA-, ConA-, or MLC-treated splenic cultures from indomethacin treated mice. Increased formation of PFC/10^6 splenocytes also were observed in treated mice (149% increase at 4 mg/kg). Indomethacin did not affect macrophage-induced inhibition of tumor cell growth (MBL- 2), but did increase phagocytosis of sheep erythrocytes. Host resistance to *Listeria* was increased in treated mice. No effect on delayed hypersensitivity was noted (Boorman et al. 1982).

Oral exposure to indomethacin (2.5, 5, or 10 mg/kg/day for 3 days) decreased formation of PFC in C57BL/6 mice after immunization to sheep erythrocytes. Studies showed a dose-dependent decrease in the number of PFC/10^6 spleen cells; decrease ranged from 43% to 97%. Similar inhibition was observed at 5 mg/kg/day indomethacin and various concentrations of sheep erythrocytes (2.5×10^8 and 5×10^8); decreases ranged from 47% to 68%. Indomethacin also inhibited antibody response to *P. aeruginosa* LPS; total response was decreased by 44% (Rojo et al. 1981).

Oral administration of 6 mg/kg/day indomethacin for 4 days produced a 32% decrease in total number of lymphocytes in Swiss male mice. No effect was noted at earlier time points (i.e., 2 or 3 days). An increase in the number of colonies/10^5 bone marrow cells (2.7- to 3.9-fold) also was noted in mice that were administered indomethacin for 4 days. Indomethacin also decreased PGE2 (25-43%) and PGF2α (41-56%) levels in bone marrow cells after 4 days of administration (Fontagne et al. 1980).

Male CBA mice were intraperitoneally injected with 0.7, 4, or 8 mg/kg indomethacin. Two to 24 hours after exposure, mice were euthanized and spleens removed. A dose-dependent increase in splenocyte proliferation was noted after 2 hours, with a 14.3-fold increase in proliferation at the highest dose tested. A time-dependent increase in proliferation was also noted when mice were treated with 4 mg/kg indomethacin, with a maximal fold change of 31.4-fold at 24 hours.

Distribution of T-cell phenotypes was not affected by indomethacin administration (Gonzalez- Cabello et al. 1987).

Kushima and colleagues (2007, 2009) evaluated effects of indomethacin in young Sprague- Dawley rats after *in utero* exposure. In 3-week old pups from dams treated with 0.25, 0.5, or

1.0 mg/kg indomethacin on GD 18-21, a significant increase (31%) in the number of spleen cells was observed in males from the highest dose group. Immunophenotyping of splenocytes showed a dose-dependent increase in the proportion of CD45RA+ cells in male pups. However, a similar

increase in peripheral blood lymphocytes was noted. No effect on serum IgM or IgG levels was reported in males or females. A significant decrease in anti-KLH IgG titers, but not IgM titers was reported in males from the highest dose group tested (Kushima et al. 2007). When doses of 0.5, 1.0, or 2.0 mg/kg indomethacin were used, a significant decrease in splenocyte IL-10 levels were reported in males; no effects on IL-6, IL-2, IL-4, TNF, or IFN-γ levels were noted in either sex (Kushima et al. 2009).

Indomethacin (1 or 2 mg/kg administered twice daily for 3 days to adjuvant induced arthritic Sprague-Dawley rats) reduced PHA-induced lymphocyte proliferation in a dose-dependent manner (data in graph). LPS-stimulated proliferation was also inhibited at both doses, however the response was partially recovered at the higher tested indomethacin dose (data in graph) (Seng et al. 1990).

Indomethacin increased the total number of cells, and number of T- and B-cells up to 14 days after birth, in newborn ddy mice intraperitoneally injected with 5 μg/g every 2 days from birth (data in graphs) (Shibuya et al. 1986).

In vitro data with cells or cell lines

Indomethacin (3 μM) inhibited proliferation of lymphocytes isolated from C57BL/6 mice (data in graph). Additionally, dose-dependent inhibition LPS-induced proliferation of isolated lymphocytes was noted (Barasoain et al. 1980).

Indomethacin dose-dependently increased male rat (strain not provided) ConA-induced lymphocyte proliferation after an 18-hour incubation (LOAEC = 1 μM). A time-course evaluation with 1 μM indomethacin showed that ConA-inducted lymphocyte proliferation was enhanced at incubation times up to 30 hours. Proliferation at exposure times ranging from 36 to 66 hours were not different from controls (Calder et al. 1991).

Indomethacin (50 nM to 50 μM) dose dependently increased LAK activity in BALB/c mouse splenocytes that were cocultured with recombinant IL-2. Increased lysis of JC tumor cells was observed, reaching a maximum response of 123.6 lytic units at 50 μM compared to 43.6 lytic units for IL-2 alone. Studies also showed that the increased response, compared to addition of IL-2 alone, was observed when culture conditions were maintained for up to 4 days. Addition of nylon wool to the culture, abrogated the

induction of LAK response observed in the presence of indomethacin (Chao et al. 1989). Increased time-dependent proliferation was observed in lymphocytes, from CBA mice, treated with 10 μg/mL indomethacin. After 6 and 24 hours, proliferation was increased 4.3- and 46.6- fold, respectively (Gonzalez-Cabello et al. 1987).

Indomethacin decreased IL-4 levels in ConA-stimulated splenocytes isolated from 3-week old male rats (LOAEL = 50 μM). No effect was noted in splenocytes from females. Decreased IL-6 splenocyte levels was observed in cells obtained from females and treated with 2.0 μM indomethacin. No effect on IL-2, IL-10, IFN-γ, and TNF-α were noted (data not shown or in graph) (Kushima et al. 2009).

Mode of action information

Indomethacin induced effects on prostaglandin synthesis was associated with several immune effects. Lala and Parhar (1988) suggested that indomethacin effects are associated with suppression of prostaglandin synthesis. Rojo and colleagues (1981) and Franceschi and colleagues (1988) proposed that indomethacin inhibition of prostaglandin synthesis leads to altered T-cell function, and NK- and antibody-dependent cytotoxicity.

Differential effects on T-cell and B-cell-induced lymphocyte proliferation were reported. A dose- dependent effect on T-cell function was reported, while an inverse effect on B-cell function was noted (Seng et al. 1990).

Indomethacin has been postulated to produce immune effects through inhibition of Th1, and to a lesser extent Th2, responses (Yamaki et al. 2003). Studies conducted by Jaramillo and colleagues (1992) supported this proposed mode of action.

Isonicotinic Acid Hydrazide (IAH) [CASRN 54-85-3]

Human Data

Data from epidemiology studies

In 19 cases of INH-induced liver failure, antibodies were present in sera of 15 patients. Anti-INH antibodies were present in 8 patients. Additionally, anti-cytochrome P450 antibodies were identified in up to 14 patients. Antibodies were not detected in patients that were treated with INH but did not have significant liver injury (Metushi et al. 2014c). In eight INH-induced liver failure patients, the dominant serum immunoglobulin isotype of anti-INH antibodies was IgG. A low titer of IgM was observed in two patients, while IgA and IgE antibodies were not detected.

Phenotyping the IgG antibody indicated that the isotype was IgG3 (Metushi et al. 2014b).

INH (1.25 μg/mL) did not stimulate PGE3 production in polymorphonuclear leukocytes or modulate PHA-stimulated mononuclear leukocytes transformations. No effect on PG2 production was observed at 5 μg/mL (Zeis 1987).

In vitro data with cells or cell lines

In a series of studies, Kucharz and colleagues studies the immunomodulatory effects of IAH. In 5 μg/mL PHA-stimulated T-cells, IAH increased cellular proliferation (16% to 27%) at concentrations ranging from 0.01 to 0.0001 mM. (Kucharz and Sierakowski 1990a). In PBMC stimulated with 5 ng/mL anti-CD3 antibody, IAH produced a biphasic response. At 1 and 10 mM IAH decreased (53.6% and 24.4%, respectively) cell proliferation. Increased cellular proliferation (18-47%) was observed at concentrations ranging from 0.0001 to 0.1 mM. A similar biphasic pattern was observed when 10 ng/mL anti-CD3 antibody was used. In T-cells stimulated with anti-CD3 antibody, PHA, or PHA with PMA, IAH also modulated proliferation in a biphasic manner (Kucharz and Sierakowski 1990a). In cells stimulated with 5 μg/mL PHA and 20 ng/mL PMA, 0.1 to 10 mM IAH decreased T-cell proliferation 17% to 46%. At 0.001 mM IAH, at significant increase (21%) in T-cell proliferation was observed (Kucharz and Sierakowski 1990d). In cells stimulated with IL-2, IAH decreased cell proliferation 0.1 and 1 mM (71% and

47%, respectively) and increased proliferation at 0.01 to 0.001 mM (8% to 12%, respectively (Kucharz 1995).

IAH also decreased T-cell IL-2 production at 0.1 and 1 mM (44.7% and 71.6%, respectively) and increased T-cell IL-2 production at 0.01 to 0.0001 mM (105% to 115%). No effect on IL-2 receptor expression in T-cells was observed (Kucharz and Sierakowski 1990b).

IAH decreased IL-1 production from human monocytes in a dose-dependent manner in the absence or presence of lipopolysaccharide (LOAEL = 0.001 mM) (Kucharz and Sierakowski 1992).

In the absence of PHA, IAH stimulated proliferation of Jurkat cells (LOAEL = 0.01 mM). In the presence of PHA (2 or 5 μg/mL), IAH stimulation was observed at higher concentrations (1 and 10 mM) while at lower concentrations no effect was observed (Kucharz and Sierakowski 1990c).

When PMA (20 ng/mL) or PMA (20 ng/mL) and PHA (5 μg/mL) were added to the media, increased Jurkat cellular proliferation was observed at 0.001 mM (32%) and 0.01 and 0.001 mM (8% and 18%, respectively) (Kucharz and Sierakowski 1990d).
INH (5 μg/mL) did not have any effect on the phagocytic activity or intracellular killing activity on polymorphonuclear leukocytes obtained from healthy volunteers (Okuyan et al. 2005).

Mode of action information

Metushi and colleagues proposed that INH produced an immune response that leads to liver injury (Metushi et al. 2014c, 2014b).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Female *Nat1/2(-/-)* mice were treated with INH either by oral gavage (100 mg/kg/day) for up to 7 days or by feed (0.2%) for 35 days. In mice treated by gavage, significant decrease in M1 macrophages and increase in M2a and M2b macrophages in cervical lymph nodes was noted. No effect on the M2c macrophages was observed. Comparatively, no effect was noted in the macrophage phenotypes obtained from mice that were exposed by feed (Metushi et al. 2014a).
INH (0.1 to 1.0 mg/10 μL) did not alter the weight of popliteal lymph nodes from C57BL/10 mice 7 days after subcutaneous injection (Kammuller et al. 1989). A lack of effect on popliteal lymph nodes from Brown Norway rats also was observed when exposed to 5 mg/50 μL INH (Verdier et al. 1990).
Four female Cbl-b-/-, C57BL/6 background that lack an E3 ubiquitin ligase, were provided diets containing 0.2% w/w INH for 5 weeks. Blood was collected to assess serum cytokine levels.
Significant decreases in serum IL-12 and IL-1α was noted in female Cbl-b-/- mice (data provided in graph). No effects on IL-1ß, IL-2, IL-3, IL-4, IL-5, IL-6, IL-9, IL-10, IL-12 (p40), IL-13, IL- 17A, eotaxin, GCSF, GMCSF, IFNγ, KC, MCP-1, MIP-1α, MIP-1ß, RANTES, and TNF-α were
observed (data provided in supplementary materials) (Metushi and Uetrecht 2014).

In vitro data with cells or cell lines

In HT-2 cells, stimulated with IL-2 (3 or 30 U/mL), increased proliferation was observed at 1 and 10 mM IAH at 30 U/mL and only at 1 mM at 3 U/mL. No effect on proliferation was observed in cells stimulated with 60 U/mL IL-2 (Kucharz and Sierakowski 1990c). Additionally, no effect on proliferation by IAH was observed in HT-2 cells stimulated with PMA (data not provided) (Kucharz and Sierakowski 1990d).

Mode of action information

No data were located.

Lead (II) Acetate Trihydrate [CASRN 6080-56-4]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

Lead (lead acetate 5.0 mg - 1.5 ng/mL, or lead chloride 0.5 mg - 0.15 ng/mL for 24 hours) significantly reduced cell vitality and/or proliferation and affected secretion of proinflammatory, TH1 and TH2 cytokines in human peripheral mononuclear blood cells that were stimulated with either heat-killed *Salmonella enteritidis* (hk-SE) or monoclonal antibodies. At lower lead levels, expression of IFN-γ, IL-1ß and TNF-α were reduced. Monoclonal antibody induced IL-4, IL-6 and IL-10 and hk-SE induced IL-10 and IL-6 levels were increased in the presence of lower lead levels. The authors suggest that lower dose lead suppresses the TH1 cytokine and the proinflammatory cytokines while the increased IL-4 and/or IL-10 production can induce and maintain a TH2 immune response (Hemdan et al. 2005).

Thirty male lead-exposed (battery recycling industry) workers with a blood lead level > 10 µg/dL and 27 unexposed healthy volunteers without any history of occupational exposure to lead were selected for this study. The serum level of IgA was found to be significantly increased in the lead-exposed group as compared to controls. No differences were observed in serum IgG and IgM levels. Both the level of nitric oxide production after stimulation with zymosan-A and the neutrophil respiratory burst as measured by nitroblue tetrazolium reduction were comparable in neutrophils from lead-exposed and unexposed volunteers (Mishra et al. 2006).

Mode of action information

Lead acetate (1 µM) induced activation of NF-κB in primary human CD4+ T lymphocytes. This lead induced activation was blocked by antibodies for p65 and p50 subunits (indicating that the p65:p50 heterodimer (NF-κB) is involved), but not by cRel. Lead acetate (100 pM – 100 µM) did not activate NF-κB in 4 different T cell lines,

suggesting that these cell lines may not be a reliable system for studying transcriptional activation in human T cells (Pyatt et al. 1996).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Lead acetate suppressed macrophage-dependent immune responses in cells taken from female BDF1 mice exposed to lead in drinking water at concentrations from 0 to 1000 ppm for 3 weeks. The T-cell dependent sheep erythrocyte primary immune response was suppressed by approximately 40-50% in all lead-exposed groups. In contrast, the *E. coli* lipopolysaccharide (T- cell and macrophage-independent) induced response, was not suppressed (Blakley and Archer 1981). Lead did not alter the ability of T-cell mitogens to induce interferon (Blakley et al. 1982).

Lead acetate effects were modulated by maternal protein intake. Fischer 344 rats were exposed to lead acetate (250 ppm) in the drinking water during breeding and pregnancy until parturition and were fed isocaloric diets (either 20% casein or 10% casein). Offspring exposed to lead and high maternal dietary protein had significantly elevated levels of both IL-4 and TNF-α (values not provided). Offspring exposed to lead and low maternal dietary protein had significantly reduced IL-4 levels compared to the lead control group (values not provided). No other changes were observed, and immune parameters measured in the dams were not affected by treatment (Chen et al. 2004).

In a study comparing immunotoxic effects of various lead salts, Balb/c mice were treated for five consecutive days between immunization and elicitation with intraperitoneal injections of 0.5 or 6 mg/kg of a lead salt. A statistically significant increase in delayed hypersensitivity (as measured by footpad swelling) was observed following administration of lead acetate (55.0% increase in footpad thickness as compared to controls; LOAEL = 6 mg/kg) (Descotes et al. 1984).

Exposure to lead acetate resulted in a decreased ability of mice to survive a sublethal dose of a virulent strain of *S. typhimurium*. C3H/HeN mice were exposed to lead acetate (5 or 10 mM) in the drinking water for up to 18 weeks. At week 16, mice were infected with *S. typhimurium*. 40% of the mice exposed to 5 mM lead acetate survived the infection with a median survival of 26 days. None of the mice treated with 10 mM lead acetate survived, with death occurring within three weeks of becoming infected. In contrast, 80% of control mice survived with a median survival of 60 days. The ability of splenocytes, cultured from the lead-treated and control mice showed a marked reduction in the production of IFN-γ (27% and 35% in mice treated with 5 and 10 mM lead acetate, respectively) and IL-12p40 (42-45% in mice treated with 5 and 10 mM lead acetate, respectively, as compared to induced control). Secretion of IL-4 by splenocytes from lead-treated mice was 3 to 3.6-fold higher than in control mice (Fernandez-Cabezudo et al.

2007).

Adult Sprague-Dawley females were treated with 500 ppm lead acetate via drinking water either early in gestation (days 3-9) or late in gestation (days 15-21). Offsping were assessed as adults. Significantly depressed DTH responses as well as increased IL-10

production, relative monocyte numbers and relative thymic weights were reported in female offspring exposed to lead during late gestation. Male offspring exposed during late gestation had significantly increased IL-12 production and decreased IL-10 production while the DTH response, relative monocyte numbers and thymic weights were unchanged compared to controls. The authors found that adherent splenocytes (likely macrophages) and T lymphocytes are the primary immune cells affected during fetal lead exposure and that gender may influence immunotoxicity due to lead exposure (Bunn et al. 2001).

Lead acetate increased IL-4 production in mice at 40 and 400 mg/L and decreased IFN-γ levels in mice at 400 mg/L. Adult Swiss mice were administered lead acetate in drinking water for 14 days. The authors concluded that low level lead exposure enhances a Th2 response while high lead levels can either stimulate Th2 immune activity or reduce Th1 activity, thus resulting in an imbalance between Th1 and Th2 activation (Iavicoli et al. 2004).

Lead acetate (100 or 1000 ppm in drinking water) did not alter the ability of splenocytes isolated from exposed male Alderly Park rats to mediate native and interferon activated natural cytotoxicity at 2,4,6 and 8 weeks following commencement of exposure. Splenic T-cell function of treated rats as determined by phytohaemagglutinin induced proliferation was comparable to control values (Kimber et al. 1986).

Lead acetate (10 mM in the drinking water for 8 weeks) did not suppress the primary direct humoral immune response to T-dependent antigen (sheep erythrocyte) and T-independent antigens (TNP-LPS, TNP-Ficoll) in several inbred (A, BALB/c, C57Bl/6, DBA/1, SJL, and NZW/NZB F1) and an outbred (CFW) strains of mice (Mudzinski et al. 1986).

Lead acetate (200 ppm either in the drinking water or given intraperitoneally for 4 weeks) decreased the number of lymphocyte cells and cellularity (i.e., number of cells per mg tissue) in the thymus, but no significant changes in either parameter were reported for the submaxillary lymph nodes. Proliferation of T cells stimulated by ConA and proliferation of B cells stimulated by LPS was increased by lead in the thymus by both routes of exposure. In the submaxillary lymph nodes, there was a decrease in the proliferation of T cells following treatment by either route (Teijon et al. 2010).

In vitro data with cells or cell lines

RAW 264.7 cells were treated with 100 ppm lead acetate for 24 hours in the presence or absence of LPS. Lead produced a statistically significant inhibition of the level of LPS-induced nitric oxide (data not provided). No effect on cytotoxicity was observed (Mishra et al. 2006).

Mode of action information

C3H/HeN mice were exposed to lead acetate (0, 5 or 10 mM in drinking water for periods of up to 18 weeks) and inoculated with a virulent strain of *S. typhimurium*. Sera were collected on days 15 and 38 post infection. The authors report that the IgG2a antibodies were elevated in control mice by day 38 post infection (0.09 ± 0.05 on day 15 vs. 0.30 ± 0.03 on day 38; an increase of 300% from day 15), but were only slightly increased in lead-exposed mice (0.11 ± 0.01 on day 15 vs. 0.16 ± 0.02 on day 38). IgG1 isotype

antibodies (an isotype induced by IL-4) were significantly elevated in lead exposed mice on day 38, as compared to control mice. The authors conclude that lead acetate induces a subtle but substantial shift toward a Th2-type immune response to infection with Salmonella organism (Fernandez-Cabezudo et al. 2007).

A single intraperitoneal exposure to lead acetate (12 mg/kg) in B6C3F1 mice produced changes in cell surface markers on discrete subpopulations of lymphoid cells from the spleen and bone marrow. The authors concluded that while the changes may not correlate with functional activity of the cells, they seemed to predict a shift to immature cell types, which correlated with the increase in progenitor cells observed (Burchiel et al. 1987).

Mannitol [CASRN 69-65-8]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

Increased urinary excretion of 9α,11ß-prostaglandin F2 and leukotriene-4 were reported in association with mannitol-induced bronchoconstriction in 14 asthmatic patients. Urinary excretion of 9α,11ß-prostaglandin F2 and leukotriene-4 increased from 61 to 92 and 19 to 31 ng

× mmol/creatinine, respectively (Brannan et al. 2006). A separate study reported that repeated challenge with mannitol induced refractoriness in asthma patients. The mannitol refractoriness was associated with maintained release of 9α,11ß-prostaglandin F2 and leukotriene-4 (Larsson et al. 2011).

Increased proportion of submucosal MCTC was observed in asthmatic individuals with airway hyperresponsiveness to mannitol compared to asthmatic individuals without responses to mannitol. The percentage MCTC increased from 18.7% to 40.3%, but the increase in the numbers of MCTC between the two groups was not significantly increased. Increased gene expression of thymic stromal lymphopoietin and carboxypeptidase AM also were reported (Sverrild et al.

2016).

Mannitol significantly increased 9α,11ß-prostaglandin F2, leukotriene-C4, and histamine release from cord blood-derived mast cells (LOAEL = 0.7 M for all endpoints). At the same tested mannitol concentrations (0.3-1.0 M), no concordant increase in lactate dehydrogenase release was observed suggesting cell viability was not affected. The ratio of 9α,11ß-prostaglandin F2 to leukotriene-C4 was 156-1 (Gulliksson et al. 2006).

Mannitol did not induce DNA damage in human leukocytes at concentrations from 1.25 to 10 mM (Frenzilli et al. 2000).

Mannitol (22 mmol/L) did not increase IL-6 or TNF-α secretion from monocytes treated

with glucose (11 mmol/glucose) for 24 hours. A similar lack of effect was observed when cells were incubated for 48 hours (Morohoshi et al. 1996).

At the highest concentration tested (100,000 μM), mannitol did not reduce cell viability in human LCLs or PBMCs. Mannitol (50,000 μM) did not modulate TNF-α, IL-6, IL-2, IL-4, IL- 10, or IFNγ release in LCLs pre-treated with phorbol 12-myristate 13-acetate/ionomycin stimulated cells (Markovic et al. 2015).

Mannitol did not inhibit growth of human granulocyte precursor cells at a concentration up to 5 mM (Holdener et al. 1983).

Mode of action information

Mannitol is shown to narrow the airway in asthmatic, but not healthy, test subjects (Brannan et al. 2001, 2003, 2000). Mannitol is proposed to increase osmolarity of airway surface liquid, leading to an increase in mediator release (e.g., histamine, prostaglandins, and leukotrienes) from inflammatory cells which induces bronchoconstriction (Brannan et al. 2006; Sverrild et al. 2016). One mediator that is proposed to be released is prostaglandin D2 from mast cells (Brannan et al. 2003, 2006).

Nickel (II) Sulfate Hexahydrate ($NiSO_4$) [CASRN 10101-97-0]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

In PBMC from five nickel allergic individuals 0.1 mM $NiSO_4$ increased IL-4 and IFN-γ production. The peak effect was lower than when PBMC were incubated with PHA (data shown in graph) (Thomas et al. 2003).

$NiSO_4$ (85 μg/mL) significantly upregulated expression of CD40, CD83, CD86, and CD54 markers on THP-1 cells. $NiSO_4$ also significantly increased production of TNF-α and IL-8 in a dose-dependent manner. IL-6 production was significantly increased after exposure to

170 μg/mL (Miyazawa et al. 2007). Ade and colleagues noted that $NiSO_4$ induced CD83, CD86, HLA-DR, and CD40 in a dose dependent manner in dendritic cells (Ade et al. 2007).

Mode of action information

$NiSO_4$ was shown to alter dendritic cell phenotypes by activation of MAPKs and NF-□B. Additionally, $NiSO_4$ induced IL-8, IL-6, and IL-12 p40 production (Ade et al. 2007; Antonios et al. 2009). Activation of the MAPK pathway may lead to upregulation of the Cys-Cys chemokine receptor, CCR7, which allows dendritic cells to migrate to the draining lymph nodes (Boisleve et al. 2004).

$NiSO_4$ has a similar capacity to stimulate polyclonal CD+4 in Ni-allergic and -nonallergic individuals. Differences in clonal expansion or presence of Ni-binding motifs in MHC class II complexes could be involved in the development of allergic contact dermatitis (Lisby et al.

1999).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Male Wistar rats were intratracheally instilled with 1, 2, 4, or 8 μmole $NiSO_4$ per rat. The rats were euthanized up to 7 days after treatment. Treatment decreased the percentage of lymphocytes in pulmonary lymphoid cells (~55% to ~40%). NK activity in lymphoid lung cells was dependent on concentration and effector:target cell ratio. NK activity was decreased 1 day after treatment of 4 and 8 μmole $NiSO_4$ at the effector to target cell ratio of 6:1. Two days after treatment suppression of NK activity was significant at doses ≥2 μmole $NiSO_4$ and at the effector to target cell ratio of 6:1. After 7 days, a significant decrease was only observed at 8 μmole.

$NiSO_4$ did not significantly modulate alveolar macrophage cytotoxic activity towards 3T12 target cells. Decreased levels of TNF-α was reported at all time points, while increased IFN-γ level was only noted after exposure to 8 μmole/rat on day 2 (data in graph) (Goutet et al. 2000).

Female B6C3F1 mice were exposed to $NiSO_4$ aerosol for 6 hours per day, 5 days per week for 65 days. The actual exposure concentrations tested were 0.027, 0.11, or 0.45 mg Ni/m3. No change in thymic weight was reported. A significant increase in the number of nucleated cell numbers from lung-associated lymph nodes (LALN) and lavage fluid, after mice were immunized with sheep red blood cells, was noted at the highest dose tested (1.72- and 3.86-fold, respectively). Nonsignificant increase in the total antibody-forming cells (AFC)/(LALN) and nonsignificant decrease in AFC/spleen, after immunization with sheep red blood cells, were also noted after $NiSO_4$ exposure. $NiSO_4$ had no effect on mixed lymphocyte response of spleen cells after exposure to mitomycin C-treated spleen cells from DBA/2 mice. No effect in mitogen- stimulation assays also were noted by $NiSO_4$ exposure. $NiSO_4$ modulated pulmonary alveolar macrophage function, as measured by phagocytosis of opsonized erythrocytes; activity was significantly increased at 0.11 mg Ni/m3 (data not provided). Comparatively, $NiSO_4$ had no effect on peritoneal macrophage phagocytosis activity at any tested dose. The highest dose of $NiSO_4$ was associated with a significant two-fold increase in the number of B16F10 tumor nodules in the lungs of treated animals. However, incorporation of radiolabeled uridine was not considered biologically significant. $NiSO_4$ did not affect splenic NK cell cytolytic activity (Haley et al. 1990).

Histopathological lesions in lungs, liver, thymus, kidneys, spleen, and lymph nodes were noted in male F344 rats intramuscularly injected with 125 μmole/kg $NiSO_4$ over 26 days. Thymus glands from rats treated with the highest dose were much smaller than controls.

Corticomedullary junction was not distinct and extensive degeneration and depletion of lymphocytes in the thymic cortex were noted. Additional tissues from these rats were evaluated further. In the lungs, large alveolar macrophages and polymorphonuclear leukocytes were noted in alveolar spaces and exudate. In the spleen and lymph nodes, lymphocytes were focally depleted in the white and red pulp (Knight et al. 1991).

Male Sprague-Dawley rats were exposed to 0.02, 0.05, and 0.1% $NiSO_4$ in drinking water for 13 weeks. Effects on splenic lymphocyte and thymocyte subpopulations were evaluated. In splenic lymphocytes, increases in the total number of T-cells (LOAEL = 0.05%) and CD8+ T-cells (LOAEL = 0.02%) were reported. For CD4+ T-cells, the number

of cells increased at 0.05% $NiSO_4$ and then decreased at 0.1% dose. An increase in the total number of B cells was noted at 0.05% $NiSO_4$. Subchronic exposure to 0.02% $NiSO_4$ also increased the percentage and absolute number of thymocyte CD8+ cells. Exposure to 0.05% $NiSO_4$ increased the total number of thymocyte cells, the percentage and absolute number of CD8+ cells, and absolute numbers of both CD4+ and B-cell populations. Exposure to 0.1% $NiSO_4$ decreased the total number of thymocytes, the percentage and absolute number of CD4+ T cells, and absolute numbers of CD8+ T cells and of B cells (Obone et al. 1999).

Male C3H/He mice were provided 0.01, 0.05, 0.1, 0.25, 0.5, or 1% $NiSO_4$ for 7 or 10 weeks. Mice were then sensitized with $NiSO_4$ for 7 days and the footpad thickness was measured. The mice were then challenged with 0.4% $NiSO_4$ and footpad swelling was measured 24 hours later. After 7 weeks of oral exposure, footpad swelling was not reduced at any of the tested doses.

However, after 10 weeks of exposure swelling was decreased (LOAEL = 0.1%) (Ishii et al. 1993).

Lymph nodes from C3H/He mice sensitized to $NiSO_4$ were incubated with various monoclonal antibodies and then injected into naïve mice. After challenging with $NiSO_4$, footpad swelling was measured. Cells treated with CD4-, Thy1.2-, or Ig-specific antibodies showed reduced swelling while cells treated with CD8 antibodies induced footpad swelling (Ishii et al. 1993).

Macrophage and PMN chemotactic activities in bronchoalveolar fluid were increased at 2 days after intratracheal instillation of 50 μg Ni per male Wistar rat. Activity then decreased until end of the experiment (14 days). Comparatively, LTB4 were maximally decreased at day 1 and then increased to control levels by day 14 (Hirano et al. 1994).

In vitro data with cells or cell lines

Spleen cells from C57BL/6 and Rag-1 deficient mice were stimulated with varying concentrations of $NiSO_4$ (concentrations not provided). Using the ELISPOT assay, IL-2, IL-4 and IFN-γ secreting cells were identified in splenic cells from C57BL/6 mice. The number of IFN-γ cells were greater than the IL-2 and IL-4 cells. At higher concentrations (≥400 μM), the numbers of IL-2 and IL-2 secreting cells decreased while those secreting IFN-γ remained high. The number of IFN-γ cells did not increase due to previous immunization of $NiSO_4$. In splenic cells from Rag-1 deficient mice, $NiSO_4$ also contained IFN-γ secreting cells. However, at higher concentrations the cell levels decreased (in comparison to wild-type). Addition of NK1.1 antibodies produced a partial depletion in the cells. Further studies showed that addition of NKG2D antibodies reduced the number of IFN-γ secreting cells in wild-type and RAG-1 deficient mice (Kim et al. 2009).

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Female B6C3F1 mice were exposed to 30, 100, or 300 mg/kg nitrobenzene for 14 days via gastric intubation. Hepatomegaly and splenomegaly were observed in mice that received 100 and 300 mg/kg nitrogenzene. Mild congestion in the red pulp areas of the spleen was noted in mice that received 100 mg/kg, while the spleen was dark red in those that received 300 mg/kg.

Absolute and relative spleen weight were significantly increased (LOAEL = 100 mg/kg). Comparatively, absolute and relative thymus weights were increased only at 100 mg/kg. The number of bone marrow cells increased in a dose-dependent manner (LOAEL = 30 mg/kg). At the highest dose tested the increase was 60% above controls. DNA synthesis and the number of CFU-GM per femur also were increased (LOAELs = 30 mg/kg). In response to sheep erythrocytes, a significant increase in spleen weight (62%) and spleen cell number (29%) was observed at 300 mg/kg, when animals were sensitized four days after nitrobenzene exposure.

Comparatively, a decrease in IgM AFCs were decreased (LOAEL = 100 mg/kg). When responses to sheep erythrocytes were observed (sensitization occurred 5 days after nitrobenzene exposure), spleen weight and cells were increased at 100 and 300 mg/kg.

However, no effects on IgG AFC were noted. When 20 days lapsed between nitrobenzene exposure and sensitization to sheep erythrocytes, no effects were reported. No effect on delayed hypersensitivity was reported at any of the tested doses. Splenic proliferation responses induced by PHA and ConA were suppressed by exposure to nitrobenzene (LOAEL = 100 mg/kg). No effect on LPS-induced proliferation were reported. Responses to DBA/2 mice spleen cells also were decreased (LOAEL
= 100 mg/kg). Using radiolabeled sheep erythrocytes, the phagocytic index was shown to be increased in a dose-dependent manner. The phagocytic activity of peritoneal cells also was increased in a dose-dependent manner (LOAEL = 300 mg/kg). The ability of spleen cells to lyse radioactivity from YAC-1 target cells also was evaluated. Nitrobenzene exposure produced a decrease in lysis capacity at 100 and 300 mg/kg at effector:target ratios of 100:1 and 30:1.

Nitrobenzene did not affect host resistance to *Streptococcus pneumonia, Plasmodium berghei,* herpes simplex 2, or B16F10 melanoma. Comparatively, host resistance to *Listeria monocytogenes* was decreased. A challenge of 6 x 10^3 *L. monocytogenes* per mouse killed 13%

of control animals and 57% of animals treated with 300 mg/kg nitrobenzene. A challenge with

1.2 x 10^4 *L. monocytogenes* increased animal death from 19% in controls to 100% at 100 mg/kg nitrobenzene and 86% at 300 mg/kg nitrobenzene (Burns et al. 1994).

In vitro data with cells or cell lines

No data were located.

Mode of action information

Two proposed targets of nitrobenzene are: (1) erythrocytes and (2) precursors to erythrocytes and other cells (e,g., granulocytes). The site of action is proposed to be the bone marrow.

Additionally, effects on T-cell function may play a role in increased susceptibility to *L. monocytogenes* (Burns et al. 1994).

o-Benzyl-p-chlorophenol (BCP) [CASRN 120-32-1]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

B6C3F1 mice were orally administered 100, 300, or 500 mg/kg BCP for 14 days. No effect on spleen or thymus weight were reported. No effect on delayed hypersensitivity response (to keyhold limpet hemocyanin), antibody response to sheep erythrocytes, serum IgM, IgA, or IgG levels, or splenic lymphocyte proliferation were noted. Absolute and relative liver weights were increased at the highest dose group. Additionally, BCP-treated mice did not develop tumors after challenge with PYB6 tumor cells (vs. controls which had a 15% tumor incidence) (Birnbaum et al. 1986).

BCP produced contact hypersensitivity in female B6C3F1 mice (Stern et al. 1991).

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Perflouorooctanoic Acid (PFOA) [CASRN 335-67-1]

Human Data

Data from epidemiology studies

Several studies have suggested that prenatal PFOA exposure is linked to immunosuppressive and immunotoxicant effects observed in offspring. Granum and colleagues (2013) reported that maternal PFOA blood levels, collected at birth, were positively associated with decreased rubella antibody-levels (β = -0.40) and an increased number of common cold episodes in children from 0-3 and 2-3 years old. Cord blood IgE levels also were suppressed in female infants with high maternal PFOA levels. However, no effects on number of 18 month-old infants with allergies (e.g., food allergy, eczema) or infections (e.g., otitis media, pneumonia, skin infections, chicken pox) were noted (Okada et al. 2012). Okada and colleagues noted that while the correlation between fetal PFOA levels and the evaluated endpoints were not available, the results suggest that PFOA produced immunosuppressive effects after prenatal exposure.

A positive association between serum PFOA in adults and development of ulcerative colitis also was reported. However, a positive association with other autoimmune diseases, such as Type 1 diabetes, lupus, multiple sclerosis, Chron's disease, and rheumatoid arthritis, was not observed (Steenland et al. 2013).

Chang and colleagues (2016) conducted a systematic review to summarize and evaluate epidemiological literature on PFOA and perfluorooctanesulfonate (PFOS) with relation to evaluated immune endpoints. Endpoints evaluated included immune biomarker levels (e.g., IgE levels, white blood cell count, and C-reactive protein), immune gene expression patterns, atopic or allergic disorders (e.g., asthma, eczema, and food allergy), infectious disease (e.g., common cold), vaccine response, and autoimmune and inflammatory conditions (e.g., ulcerative colitis, rheumatoid arthritis, and osteoarthritis). The authors stated that the totality of the data limited development of a conclusion on the causal relationship between PFOA and/or PFOS exposure and evaluated endpoints due to inconsistent results and confounding factors.

In vitro data with cells or cell lines

Studies with human cells or human-derived cell lines indicate that PFOA modulates cell activation and cytokine production. In human PBMC, PFOA significantly increased the percentage of viable cells at concentrations <125 μg/mL. At higher concentrations (250 and
500 μg/mL), a significant decrease in cell viability was reported (values not reported). No effects on T-cell proliferation (NOAEL = 1 μg/mL) or, TNF-α or IL-6 release (NOAEL = 1 μg/mL) were noted. PFOA also increased monocyte differentiation in HL-60 cells (LOAEL = 100 μg/mL) (Brieger et al. 2011). Comparatively, PFOA decreased TNF-α, IL-4, and IL-10 (LOAEL
= 1 μg/mL, 10 and 10 pg/mL, respectively) in peripheral leukocytes. PFOA also decreased TNF- α (LOAEL = 10 μg/mL) production in THP-1 cells (value not reported). PFOA did not affect IL- 2 production in Jurkat cells (value not reported) (NOAEL = 0.005 μg/mL) (Corsini et al. 2011, 2012; Midgett et al. 2015).

Mode of action information

Direct modulation of NF-□B has been implicated in modulation of cytokine production and secretion (Corsini et al. 2012). PFOA interaction with the PPARα receptor also was implicated in immunomodulatory effects in human cells. Receptor interaction was associated with reduced p65 phosphorylation and NF-□B-mediated transcription (Corsini et al. 2011). The extent the role of PPARα receptor activation plays in human effects is unclear given the low level of human receptor expression (Corsini et al. 2014).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Animal studies suggest that PFOA exposure can affect innate and adaptive immune functions *in vivo*. Dietary exposure to PFOA (0.02% w/w) for 7 days significantly decreased spleen and thymus weight, and splenocyte and thymocyte levels in wild-type C57Bl/6 mice. Spleen weight and splenocyte numbers were not affected in PPARα-null mice (Yang et al. 2002).

Table 1. Data from Yang et al. (2002)

Group and Treatment	Body weight (g)	Spleen weight (g)	Splenocyte number (x 10^6)	Thymus weight (g)	Thymocyte number (x 10^6)
Wild-type mice					
None	24.5 ± 1.58	0.082 ± 0.006	68.8 ± 16.8	0.061 ± 0.014	81.0 ± 28.2
PFOA	21.0 ± 0.74**	0.050 ± 0.001***	15.3 ± 5.84***	0.013 ± 0.001***	12.8 ±7.98***
PPARα-null mice					
None	23.6 ± 2.9	0.064 ± 0.021	84.0 ± 19.3	0.054 ± 0.006	88.3 ± 7.04

PFOA	23.5 ± 1.0†	0.054 ± 0.015	73.8 ± 26.2†††	0.033 ± 0.005***†††	54.0 ± 12.7**†††

All values are means ± SEM for four animals in each group. **P<0.01, ***P<0.001 compared to the corresponding control.

†P<0.05, †††P<0.001 compared to the corresponding wild-type group.

Dose response studies in C57Bl/6N mice reported that PFOA decreased absolute and relative spleen weights (LOAEL = 7.5 and 15 mg/kg/day, respectively) and absolute and relative thymus weights (LOAEL =15 mg/kg/day for both endpoints). Organ weight effects were generally reversed by 15 days after exposure was terminated (DeWitt et al. 2008). No effect on organ weights was reported in PPARα knockout mice treated with 7.5 or 30 mg/kg/day PFOA for 15 days (DeWitt et al. 2016).

PFOA exposure in drinking water was associated with reduced IgM antibody titers in C57Bl/6J and C57Bl/6N mice (DeWitt et al. 2008, 2016). Removal of the adrenal glands in C57Bl/6N mice did not reverse reductions in IgM antibody titer levels, suggesting that the observed suppression was not in response to corticosterone production (DeWitt et al. 2009).

Modulation of the complement system was observed in C57Bl/6 mice administered PFOA- treated diets. In mice provided diets containing PFOA for 10 days, activity of the classical and alternative pathways of the complement system was decreased (N/LOAEL = 0.01%/0.02%, respectively). Serum C3 levels also was decreased by PFOA (N/LOAEL = 0.01%/0.02%, respectively). Results showed that PFOA-induced hepatotoxicity was associated with activation of the complement system (Botelho et al. 2015).

Dietary PFOA (0.02% w/w) for 10 days significantly decreased total white blood cell count (72%) and number of macrophages in the bone marrow (12.2%) (Qazi et al. 2009). Exposure of mice to 0.002% PFOA for 10 days modulated levels of intrahepatic immune cells. The total number of all leukocytes (CD45+) was increased 2-fold in treated mice. Additionally, changes in cell numbers other cell types also were noted (e.g., granulocytes and myeloid suppressor cells). Hepatic levels of TNF-α (33%), IFN-γ (37%), and IL-4 (31%) were decreased in treated mice; IL-6 levels were not affected (Qazi et al. 2010).
Hu and colleagues reported effects in offspring of dams exposed to PFOA. Dams were gavaged with 0.02, 0.2, or 2 mg/kg PFOA from before pregnancy to PND 21. Splenic CD4+CD25+Foxp3+ T cells was decreased by 22% in exposed offspring (LOAEL = 2 mg/kg) (Hu et al. 2012).

In vitro data with cells or cell lines

Reduced lymphocyte proliferation was observed in cells isolated from C57Bl/6 mice treated with diets containing 0.02% PFOA for 7 days. No effect was observed in lymphocytes isolated from PPARα-null mice also provided diets containing 0.02% PFOA (values not provided) (Yang et al. 2002). Increased *ex vivo* production of TNF-α in cells isolated from peritoneal cavity (2.2-fold) and bone marrow (1.7-fold), and IL-6 in cells isolated from peritoneal cavity (2.6-fold) was observed in mice treated with 0.02% dietary PFOA for 10 days. Comparatively, TNF-α production was decreased (0.8-fold) in cells isolated from spleen of treated animals (Qazi et al.
2009). IgM or IFN-γ production levels were not modulated in intrahepatic immune cells isolated from male C57Bl/6 mice provided diets with 0.002% (w/w) PFOA for 10 days (Qazi et al. 2010).
Ex vivo co-cultures of splenic CD4+CD25+ and CD4+CD25- T cells offspring gestationally and lactationally exposed to PFOA were assessed for effects on IL-10 production. Results showed IL-10 produced was significantly decreased at all doses 61%-75% in cells obtained from male offspring (LOAEL = 0.02 mg/kg). *Ex vivo* measurement of autoreactivity antibodies in female mice gestationally and lactationally exposed to 0.02 and 2 mg/kg PFOA showed an decrease (26%) in anti-ssDNA (Hu et al. 2012).

Mode of action information

PFOA suppresses T-cell-dependent and T-cell-independent antibody responses (DeWitt et al. 2012). The role of PPARα in PFOA-induced immunosuppression may be strain dependent (Corsini et al. 2014). PFOA-induced effects on humoral immunity may occur through effects on B-cell/plasma cell function (DeWitt et al. 2016). Direct effects on immune cells also are a proposed mode of action of PFOA (Corsini et al. 2014).

The lack of impact of removal of the adrenal gland on PFOA-induced inhibition of IgM antibody titer levels suggests that the observed effects are not dependent on elevated corticosterone levels in mice (DeWitt et al. 2009).

Effects on lymphoid organ weights and measures of immune function (i.e., thymus and spleen) indicate that they are differentially sensitive to PFOA effect. The biological basis for this difference is not known (DeWitt et al. 2016).

Toluene [CASRN 108-88-3]

Human Data

Data from epidemiology studies

No difference was noted in lymphocyte counts between individuals with or without toluene exposure (Akbas et al. 2004).

In vitro data with cells or cell lines

No data were located.

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Male C3H mice were exposed to 9 ppm toluene (nose-only inhalation exposure) for 30 minutes on study days 0, 1, 2, 7, 14, 21, and 28. Mice also were immunized with ovalbumin. Toluene exposure significantly increased total cell (3-fold) and macrophage (3.1-fold) count in BAL 24 hours after final exposure. No effect on lymphocyte count was noted. BDNF level in BAL was increased in toluene-exposed mice that were immunized with ovalbumin (data in figure). Splenic ratio of CD4 and CD8 cells in control and toluene-exposed mice were not significantly different;
3.95 and 4.14, respectively. Treatment with ani-CD4 antibody decreased the ratios to 0.65 and 0.49, respectively. Toluene exposure significantly increased plasma levels of nerve growth factor (data in figure), but did not increase plasma BDNF levels (data not provided) (Fujimaki et al. 2009).
Male C57BL/10 and B10.BR/Sg mice were inhalationally exposed to 0, 5, and 50 ppm toluene for 6 hours per day, 5 days per week for 6 weeks. Subgroups of control and treated mice were administered ovalbumin prior to exposure. Toluene exposure did not impact ConA- or LPS- induced proliferation of spleen cells from C57BL/10 mice. While

no effect of ConA was noted in B10.BR/Sg (not treated with ovalbumin) mice spleen cells, 50 ppm toluene significantly increased the LPS-induced proliferation of spleen cells. Comparatively, 50 ppm toluene significantly decreased spleen cell proliferation in B10.BR/Sg mice treated with ovalbumin (data in graphs). Toluene did not alter expression of CD3, CD19, and CD11b (data not provided).

Forkhead box P3 (Foxp3) transcription was significantly increased in spleen cells from B10.BR/Sg mice exposed to 5 ppm toluene and ovalbumin, when compared to controls and those not treated with ovalbumin. No effect on GATA3 or T-bet expression was noted (Fujimaki et al. 2010).

Pregnant C3H/HeN mice were exposed to 50 ppm toluene via inhalation on GD 14-18. Additionally, male offspring of unexposed dams were exposed to 50 ppm toluene on PND 2-6 or 8-12. The following table summarizes the effects observed in male offspring on PND 21.

Table 1. Summary of effects in male offspring

Origin	Biomarker	GD 14-18	PND 2-6	PND 8-12
Plasma	IgG2a	No effect	Decrease	Increase
	IgG1	Decrease	Decrease	Decrease
Spleen	CD4+ lymphocyte subset	No effect	Decrease	Decrease
	CD8+ lymphocyte subset	No effect	No effect	Decrease
	T-bet mRNA	No effect	Decrease	Decrease
	Foxp3 mRNA	No effect	Decrease	Decrease
	GATA3 mRNA	No effect	No effect	No effect

On PND 42, IgG2a levels were decreased in mice exposed to 50 ppm toluene on PND 8-12. No effect on IgG1 was noted. CD19+ B-lymphocytes and CD4+ T-lymphocytes were significantly decreased, while CD3+ T-lymphocytes were increased at PND 42 after exposure on PND 8-12. Additionally, T-bet expression was significantly decreased, while no effects on GATA3 or Foxp3 mRNA expression were reported (Win-Shwe et al. 2012a). Pregnant C3H/HeN mice were exposed to 5 or 50 ppm toluene via inhalation on GD 14-18. Additionally, male offspring of unexposed dams were exposed to 5 or 50 ppm toluene on PND 2-6 or 8-12. In the hippocampus of PND 21 male offspring, TNF-α and NF-κB mRNA were significantly increased in mice exposed to 50 ppm on PND 2-6 when compared to controls (data in graphs). TNF-α, CCL3, and NF-κB were increased in mice exposed to 5 ppm on PND 8-12 (data in graphs) (Win-Shwe et al. 2012b).

In vitro data with cells or cell lines

Toluene (500 μM) exposure significantly increased ConA- (1.8-fold) and LPS- (2.1-fold) induced proliferation of spleen cells from female C57BL/6 mice. However, at the same concentration toluene did not modulate NK activity or suppress CTL formation (Grayson and Gill 1986).

Mode of action information

Low-level (5 ppm) inhalational exposure to toluene activates the STAT6, STAT5, and Foxp3 signaling pathway to enhance Th2-related and T_{reg}-related responses in B10.BR/Sg mice treated with ovalbumin (Fujimaki et al. 2010). Toluene also enhanced NF-□B, STAT5, and NF-AT in thymus cells of C3H/HeN mice inhalationally exposed to toluene (Liu et al. 2010).

Toluene modulation of IL-2 synthesis, after oral exposure, may play a role in observed immunotoxic effects (Hsieh et al. 1989).

Tributyltin Chloride (TBTC) [CASRN 1461-22-9]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

TBTC dose-dependently decreased the percentage of colony forming unit-granulocyte macrophage (CFU-GM) colonies at concentrations ranging from 0.001 to 3.3 μM (data not provided) (Carfi et al. 2007).

Cytokine release from human lymphocytes was assessed in whole blood obtained from three donors. IFN-γ was evaluated in blood from two donors after PHA stimulation for 72 hours. Comparatively, TNF-α was evaluated in blood from three donors after LPS stimulation for 72 hours. Overall, IFN-γ and TNF-α was modulated (i.e., either increase or decrease release) in all tested samples (Carfi et al. 2007).

Long-term cultures of human bone marrow cells were incubated with 0.001 μM TBTC in the presence or absence of a cytokine mixture for 7 or 14 days. A significant decrease in the percentage of CD19+CD22+ cells, in the absence of effects on the total lymphocyte population or percentage of T-cell subsets was reported after 7 and 14 days. Addition of cytokine mixture had no effect on TBTC effects. TBTC also induced cell death in CD19+ lymphocytes, in the absence of PPAR-γ receptor expression (Carfi et al. 2010).

The IC50s for cell viability in human LCLs or PBMCs were 0.25 and 0.33 μM, respectively. TBTC (0.1 μM) did not modulate TNF-α, IL-2, IL-4, or IL-10 release in LCLs pre-treated with phorbol 12-myristate 13-acetate/ionomycin stimulated cells. Comparatively, TBTC significantly decreased IL-6 and IFN-γ release (Markovic et al. 2015).

Mode of action information

In vitro toxicogenomic studies in Jurkat cells (human lymphoblastic T-cell line) showed that TBTC activated cellular stress response and retinoic-acid mediated response genes (Shao et al. 2013).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

In a 2-week study, male Wistar rats were provided diets containing 15, 50, or 150 ppm TBTC. A dose-related decrease in relative and absolute spleen and thymus weights were reported (LOAEL
= 50 and 15 ppm, respectively). Concurrent to the change in thymus weight, a decrease in thymic cell counts also was observed (LOAEL = 50 ppm). However, no signs of increased lymphocyte destruction in the spleen was observed. A dose-related increase in relative liver weight was reported (LOAEL = 50 ppm). Decreased thymus weight also was observed in rats fed 100 ppm

TBTC for 4-weeks (43% of control weight); no effects on spleen or liver weight were noted (Snoeij et al. 1985).

In utero and lactational exposure effects of TBTC (0.025, 0.25, or 2.5 mg/kg/day) were evaluated in Sprague-Dawley rats. Dams were orally dosed with TBTC from GD 8 until weaning. After weaning, pups were orally exposed to the same dose as the dam until sacrifice (up to PND 90). In males, a significant decrease in spleen weight was only observed in pups treated with 0.25 mg/kg/day on PND 30. A significant decrease in thymus weight also was noted on PND 30 (LOAEL = 2.5 mg/kg/day) (Cooke et al. 2004). Serum IgM levels were increased in 30- and 60-day old female offspring, while IgA, IgM, IgG, and IgG2a levels were increased in 90-day old male rats (Tables 1 and 2) (Tryphonas et al. 2004).

Table 1. Serum IgM levels in 30- and 60-day old females†.

	30-day old females				60-day old females			
	Control	0.025 mg/kg/day	0.25 mg/kg/day	2.5 mg/kg/day	Control	0.025 mg/kg/day	0.25 mg/kg/day	2.5 mg/kg/day
IgM	51.6 ± 8.8	41.2 ± 6.8	39.6 ± 5.8	66.5 ± 9.9	34.0 ± 3.2	63.8 ± 5.8	68.1 ± 16.4	73.0 ± 15.0

†Values provided as pg Ig/mL serum × 10^4 (standard error of the mean ± standard error).

Table 2. Serum immunoglobulin levels in 90-day old males†

	Control	0.025 mg/kg/day	0.25 mg/kg/day	2.5 mg/kg/day	Pearson product moment correlation
IgA	32.0 ± 8.8	13.9 ± 3.3	9.7 ± 3.4*	11.9 ± 1.6	>0.05
IgM	46.2 ± 8.9	65.1 ± 4.9	69.6 ± 5.8	232.5 ± 90.1*	0.00168
IgG	96.8 ± 9.6	184.2 ± 86.7	194.6 ±	314.1 ±	0.0134

			25.7*	57.5*	
IgG1	41.5 ± 8.6	77.2 ± 28.6	85.2 ± 18.6	58.1 ± 15.9	>0.05
IgG2a	53.1 ± 5.7	59.1 ± 6.3	50.8 ± 4.6	31.3 ± 4.4*	0.00041
IgG2b	34.1 ± 3.3	39.1 ± 5.6	39.3 ± 3.5	31.6 ± 4.2	>0.05
IgG2c	13.6 ± 1.7	20.6 ± 3.6	41.0 ± 19.4	20.9 ± 2.2	>0.05

†Values provided as pg Ig/mL serum × 10^4 (standard error of the mean ± standard error).

* Significantly different from control.

The number and percentage of NK cells was increased in 30-day female and male offspring (LOAEL = 2.5 mg/kg/day). A dose-dependent increase in the number and percentage of NK cells also was noted in 90-day male rats. In 60-day female offspring an increase in the percentage of CD4+8+ T lymphocytes (LOAEL = 0.25 mg/kg/day). No anti-sheep erythrocyte IgM response or lymphoproliferative activity of splenocytes in response to mitogen stimulation was noted in 60- day old female rats or 90-day old male rats (data not provided). Delayed-type hypersensitivity to oxazolone was increased in 90-day old male rats at 0.025 and 0.25 mg/kg/day and decreased at

2.50 mg/kg/day. Mean colony forming *L. monocytogenes* bacteria was non-linearly increased at 48 hours post-infection and statistically significant in pairwise comparisons (0.25 mg/kg/day) in 60-day old females. In 90-day old males, a non-linear dose–response trend 3 days after infection was reported. No effects in serum levels of IL-2, TNF-α, IFN-γ, and IL-1ß were reported in males or females. A non-linear dose-response increase in NK activity in 60-day females was reported (Tryphonas et al. 2004).

Lactational exposure in mice to TBTC also impaired innate immunodefenses in offspring. C57BL/6 pregnant mice were given drinking water with 15 or 50 µg/mL TBTC from parturition to weaning. Clearance of *Escherichia coli* K-12 from the peritoneal cavity and spleen of offspring treated with 15 µg/mL TBTC was significantly decreased (Kimura et al. 2005).

ICR mice were orally dosed with 0.5, 4, or 20 mg/kg TBTC for 28 days. Relative spleen and thymus weights were significantly decreased at the highest dose tested (46% and 59% decrease, respectively). TBTC also decreased the number of plaque forming cells in response to exposure to sheep red blood cells (LOAEL = 4 mg/kg). TBTC also suppressed delayed-type hypersensitivity response to sheep red blood cells when assessed 24 and 48 hours after injection (LOAEL = 4 mg/kg). TBTC suppressed T-lymphocyte proliferation in a dose dependent manner (LOAEL = 20 mg/kg). Increased percentage of early- and late-stage thymocyte apoptosis, and expression of Fas protein expression in proteins also were noted (LOAEL = 4 mg/kg) (Chen et al. 2011).

Esophageal tubing of male C3H/Hen mice with 10 or 100 ppm TBTC for 1 week was associated with decreased NK activity. NK activities were inhibited 36% to 46% at effector:target (YAC-1 cells) ratios of 25:1 and 50:1, respectively. A significant decrease in the percentage of large granular lymphocytes (~60%) also was noted 1 week after end of treatment (Ghoneum et al.
1990).

In vitro data with cells or cell lines

Neutrophils and macrophages from mice lactationally exposed to TBTC (15 or 50 µg/mL) were isolated from peritoneal exudates. Bacterial binding to isolated neutrophils from offspring treated with 50 µg/mL TBTC was significantly decreased (data not provided). Comparatively, bacterial binding was increased in macrophages isolated from offspring treated with 50 µg/mL TBTC. Decreased phagocytosis (LOAEL = 15 µg/mL) and killing activities (15 µg/mL) only were observed in neutrophils. No effect on IL-1ß, IL-6, or TNF-α production was noted from macrophages or neutrophils. MCP-1 production was significantly increased in neutrophils isolated from offspring treated with 50 µg/mL TBTC (Kimura et al. 2005).

Rat and mouse spleen cells were treated with TBTC for 24 hours and then LPS or PHA for 48 hours. Then, mitogen stimulation was assessed by 5-bromo-2'-deoxyuridine incorporation.

TBTC inhibited cellular proliferation for both species; the inhibitory response was more potent in mice cells vs. rat cells (IC50 with LPS: 0.0025 vs. 0.007 μM, IC50 with PHA: 0.002 vs.

0.007 μM). TBTC also inhibited rat spleen proliferation that was stimulated by ConA (no data provided). TBTC also inhibited anti-CD3 antibody stimulation of mouse lymphocyte proliferation (IC50 > 0.1 μM) (Carfi et al. 2007).

NK activity was dose-dependently inhibited in splenic lymphocytes incubated with 0.01 to

1 ppm TBTC. The LOAEL values at effector:target ratios of 25:1 and 50:1 were 0.05 and 0.01 ppm, respectively. Decreased viability of splenic lymphocytes also was reported after exposure to TBTC (LOAEL = 0.1 ppm) (Ghoneum et al. 1990).

Mode of action information

In vivo effects of TBTC on the thymus of orally treated rats are proposed to be due to the metabolite dibutyltin chloride (Snoeij et al. 1988).

The role of apoptosis is not clear. In one study the authors indicated that apoptosis does not appear to be involved in inhibition of immature thymocyte proliferation, which may lead to thymus atrophy (Gennari et al. 1997). In a separate study, the authors proposed oxidative stress plays a role in TBTC-caspase-dependent apoptosis in murine thymocytes (Sharma and Kumar 2014).

In vitro studies suggest that TBTC promotes Th2 polarization via depletion of glutathione in antigen-presenting cells, which leads to modulation of IL-10 and IL-12 production (Kato et al. 2006).

Urethane [CASRN 51-79-6]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

The IC50s for cell viability in human LCLs or PBMCs were 82,329 and 140,768 μM, respectively. Urethane (5000 μM) did not modulate TNF-α, IFN-γ, IL-2, IL-4, IL-6, or IL-10 release in LCLs pre-treated with phorbol 12-myristate 13-acetate/ionomycin stimulated cells (Markovic et al. 2015).

Urethane dose-dependently decreased the percentage of CFU-GM colonies at concentrations greater than 1000 μM (data provided in graph) (Carfi et al. 2007).

Cytokine release from human lymphocytes was assessed in whole blood obtained from four donors. IFN-γ was evaluated in blood from three donors after PHA stimulation for 72 hours. Comparatively, TNF-α was evaluated in blood from four donors after LPS stimulation for 72 hours. IFN-γ was modulated (i.e., either increase or decrease release) in a single tested sample. TNF-α was not modulated any of the tested samples (Carfi et al. 2007).

Mode of action information

No data were located.

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Inbred A/J mice were administered urethane (1 mg/g) via intraperitoneal injection. A biphasic response on splenic NK cell activity was noted. At one day after the injection activity was decreased 60%, activity then increased (decreased 35%), and then remained decreased until 14 days after exposure (decreased 98%). Spleen size was initially reduced, but then increased to control levels. Mitogen response (against YAC-

1 or RL♂1 target cells) was initially depressed after urethane exposure and then returned to control levels (Gorelik and Herberman 1981a).

Inbred A/J mice (5-24 days old) were administered urethane (0.5 mg/g or 1 mg/g) up to 24 days old. In all tested groups, splenic NK activity was inhibited without effects on cellularity on spleens. Decreased NK activity remained until at least 8-10 weeks of age (Gorelik and Herberman 1981a).

Inbred A/J, CBA/J, and C57BL/6 mice were administered urethane (1 mg/g) via intraperitoneal injection. One day after injection, cytotoxicity (against YAC-1 target cells) of A/J and CBA/] spleen cells was significantly decreased (63% and 25%, respectively). Activity was similar to control levels at day 4. Activity then decreased in splenic cells from A/J mice (58%), while a

similar effect in cells from CBA/J mice was not observed. No effect on activity was observed in C57BL/6 mice (Gorelik and Herberman 1981b).

Female B6C3F1 mice were administered 1, 2, or 4 mg/g urethane over a 14-day period via intraperitoneal injection. Decreased spleen weight (decreased 47%) and thymic atrophy (decreased 40%) were observed at 4 mg/g. Splenic lymphoproliferative response to ConA was decreased at 4 mg/g (42%). Responses to PHA and spleen cells from DBA mice were similar to controls. Delayed hypersensitivity responses also were not affected by exposure to urethane.

Serum immunoglobulin levels and antibody responses to sheep erythrocytes and LPS were decreased in mice administered 4 mg/kg (decreased 61% and 46%, respectively). Macrophage cytostasis of MBL-2 target cells was decreased (LOAEL = 1 mg/g). However, phagocytosis and bactericidal activity against *S. aureus* was not affected. Pluripotent stem cells proliferation was inhibited at all doses. Urethane decreased NK activity against all YAC-1 target to cell ratios at all doses (Luster et al. 1982).

C57BL/6J dams were subcutaneously injected with 0.05 or 0.1 mg/g urethane on GD 7-17. Offspring were evaluated 8 weeks after parturition. Increased relative spleen weight was reported for the litter at 0.05 mg/g urethane. When evaluated based on sex, only an increase in relative thymus weight was observed at 0.05 and 0.1 mg/g. Decreased white blood cell count was also observed (LOAEL = 0.05 mg/g). No effect on lymphoproliferative responses or NK cell activity was noted. However, a decrease in the levels of plaque forming cells in response to sheep erythrocytes was noted (LOAEL = 0.1 mg/g) (Luebke et al. 1986).

C57BL/6J offspring were subcutaneously injected with 0.2 mg/g urethane on PND 5-14. No effects on organ weight or lymphoproliferative responses were noted. NK cell activity was decreased at an effector:target (YAC-1) ratio of 50:1. Splenic cellularity was increased in female offspring and decreased in male offspring (Luebke et al. 1986).

Female C57BL/6J mice were subcutaneously injected with 1, 2, or 4 mg/g urethane. Significant reduction in absolute (LOAEL = 1 mg/g) and relative (data not provided) spleen weights were observed. Additionally, absolute thymus weight was decreased (LOAEL = 4 mg/g). Dose- dependent reduction in leukocyte number was noted, but differential counts of white blood cells were not altered. Lymphoproliferative responses,

induced by ConA, PHA, and LPS, were suppressed by urethane (LOAELs = 1, 1, and 4 mg/g, respectively). were noted.

Lymphoproliferative responses to allogenic cells (mitomycin C treated CBA/J mouse spleen cels) were not affected by urethane exposure. NK cell activity was not affected at any effector:target (YAC-1) ratio. Splenic cellularity of mice treated with urethane and sheep erythrocytes was decreased (LOAEL = 2 mg/g) without effects on PFC/spleen or PFC/splenocytes. Decreased DTH index (to keyhole limpet hemocyanin) was decreased in urethane treated mice (LOAEL = 4 mg/g) (Luebke et al. 1987).

mRNA expression of interleukins and TNF-α were evaluated in spleens of male Wistar rats exposed to 1500 mg/kg urethane. Increased expression of IL-6 was noted, while decreased expression of IL-1ß and TNF-α were reported. No effects on IL-2 expression were observed (Bette et al. 2004).

Urethane (10%) did not deplete ear epidermis Ia-positive LCs after male BALB/c mice were treated with topical application. Similarly, urethane did not alter the density of ß-glucuronidase- positive LC in C57BL mouse tails topically treated for 1 or 3 weeks (Halliday et al. 1988).

Urethane administration to pregnant ICR mice (1.5 mg/g subcutaneous injection on GD 10) produced a transient decrease in dam thymocyte cell count. At 3 days after treatment, a significant decrease in cell count was noted. By 5 days after treatment, the cell count had recovered to control levels (data in graph). A similar phenomenon was noted with thymocyte phenotypes; decrease in CD4+8+ thymocytes (88%) at day 3 after treatment was recovered by day 5. Transient changes in dam splenocyte cell count and splenocyte phenotype CD4+8-, CD4- 8+, and CD4-8- also were reported. Gene expression analyses identified changes in spleen gene expression due to urethane exposure with or without immune stimulation (FCA). Increased expression of TGFß3 was observed in the presence or absence of immune stimulation one day after treatment. IGF-I, IGF-II and IL-2 were also differentially expressed (Sharova et al. 2002).

In vitro data with cells or cell lines

Rat and mouse spleen cells were treated with urethane for 24 hours and then LPS or PHA for 48 hours. Then, mitogen stimulation was assessed by 5-bromo-2'-deoxyuridine incorporation.

Urethane did not inhibit cellular proliferation in either species (data not provided). Urethane also did not modulate rat spleen proliferation that was stimulated by ConA or inhibit anti-CD3 antibody stimulation of mouse lymphocyte proliferation (data not provided) (Carfi et al. 2007).

Mode of action information

In vitro and *in vivo* studies suggest that urethane metabolism by cytochrome P450 is needed to produce the observed immunomodulatory effects (Cha et al. 2000). Macrophage effects are based on urethane effects on the inductive phase of immune responses (Foris et al. 1983).

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

Vanadium pentoxide (25 – 400 μM) inhibited cell proliferation and induced cell apoptosis in a dose and time-related manner in the IL-2-independent human NK cell line, NK-92MI. Cell proliferation was maximally inhibited (78%) at 400 μM vanadium pentoxide, and the percentage of cells undergoing apoptosis increased at 12 and 24 hours of exposure (51.2 and 64.7%, respectively) as the concentration of vanadium pentoxide increased. IL-2, IL-10 and IFNγ secretion were all inhibited by vanadium pentoxide after 24 hours at the highest concentration tested. IL-2 secretion also was inhibited after 12 hours. Expression of CD25 significantly increased above background starting at 50 μM, reaching a maximal migration inhibitory factor (MIF) of 47.4% at 400 μM. A similar pattern was observed for IL-15Rα, with a maximal MIF of 55.2% at 400 μM. Fas expression began to increase at 100 μM and reached a maximal MIF of 48.9% at 400 μM, while FasL peaked at 200 μM (62.1%). Jak3 phosphorylation was increased at 12 and 24 hours after treatment with 200 and 400 μM vanadium pentoxide (data in figure), and intracellular staining showed a strong presence of pJak3 in the internal cell membranes after treatment. (Gallardo-Vera et al. 2016).

Mode of action information

Vanadium in the +2, +3, and +4 (but not the +5) valence states interacted with human FMLP- activated neutrophils and statistically significantly increased the formation of hydroxyl radicals, with additional augmentation observed in the presence of sodium azide (values not provided) (Fickl et al. 2006).

Vanadium pentoxide induced toxic effects on the IL-2-independent human NK cell line, NK- 92MI, through dysregulation of signaling pathways mediated by IL-2 via increased

PTEN and decreased SHP1 expression (Gallardo-Vera et al. 2018).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

Male F344 rats were exposed to vanadium pentoxide (100 μg V/m^3) via inhalation, 5 hours per day for 5 days. The animals were infected with Listeria following the 5-day exposure and the bacterial burden assessed at 24, 48 and 72 hours, post-infection. Vanadium pentoxide did not have any significant effect on Listeria burdens at any of the timepoints observed (Cohen et al. 2007).

Male CD-1 mice were exposed to vanadium pentoxide (0 or an average of 1436 μg/m^3) via inhalation, 1 hour per day, 2 times per week over 12 weeks. An increase in the number (3.8±0.12 vs. 2.1±0.12 μm per field) and the size (36±0.52 vs. 25±0.35 μm) of megakaryocytes in the

spleen was observed in vanadium pentoxide exposed mice, as compared to controls. These same types of changes were also observed in the bone marrow (values not provided). No statistical difference was observed in spleen weight between treated and control mice (Fortoul et al. 2008). When male and female CD-1 mice were exposed to vanadium pentoxide (0 or 1.4 mg/m^3) using the same protocol as in Fortoul et al., 2008, a sex difference was observed in the expression of Ki-67, a specific proliferation marker for lymphocytes. The percentage of Ki-67 immunopositive lymphocytes increased in male mice (38.86, 41.75 and 41.91%) after 4, 8 and 12 weeks of exposure, respectively, with both cytoplasmic and nuclear expression of Ki-67 observed. In female mice, the percentage of proliferating lymphocytes increased only after the first week of exposure (34.87%) and the signal was observed only in the nucleus. Subsequent exposures did not produce significant changes in the percentage of proliferating cells in females. The authors concluded there is a role for sex hormones in potential protection against vanadium immunoxicity (Rodriguez-Lara et al. 2016).

Male CD-1 mice were exposed to vanadium pentoxide (0 or an average of 1.4 mg/m^3) via inhalation, 1 hour per day, 2 times per week over 12 weeks. Spleen weight of vanadium exposed animals peaked at 9 weeks (546 ± 45 vs. 274 ± 27 mg in controls) and progressively decreased afterwards (321 ± 39 mg at 12 weeks vs. 298 ± 35 mg in controls). The spleens of vanadium exposed animals had histological changes that included increased numbers of lymphocytes and megakaryocytes as compared to controls. The number of $CD19^+$ cells was also increased within the hyperplastic germinal node (values not provided) and the mean hepatitis B surface antigen levels in immunized control mice was greater than in the exposed hosts (OD=0.39 ± 0.03 vs. 0.11 ± 0.05). The authors concluded that vanadium pentoxide induces functional changes in the spleen which appear to result in effects on the humoral immune response (Pinon-Zarate et al. 2008).

Male CD-1 mice were exposed to vanadium pentoxide (0 or an average of 1.4 mg/m^3) via inhalation, 1 hour per day, 2 times per week over 4 weeks. The expression of CD11c in the thymic medulla was decreased in vanadium pentoxide exposed mice, as compared to controls (values not provided), based on immunohistochemistry. Flow cytometry also

demonstrated a decrease in $CD11c^+$ and $MHC\text{-}II^+$ cells in vanadium pentoxide exposed mice, as compared to controls (values not provided). The decrease was both, in terms of number and in mean fluorescence intensity values (Ustarroz-Cano et al. 2012).

Male F344/N rats and female B6C3F1 mice were exposed to 0, 4,8, or 16 mg/m^3 vanadium pentoxide, via inhalation, 6 hours per day, 5 days per week for 16 days. Pulmonary inflammation was assessed via analysis of BAL fluid. Significant alterations in the percentage of recoverable macrophages and neutrophils (NOAEL 4 mg/m^3), and increased lung protein and lysozyme in male rats (LOAEL 4 mg/m^3) were observed. In female mice, an increase in lymphocytes, protein and lysozymes was observed (LOAEL 4 mg/m^3). No effects were observed on systemic immunity as evidenced by a normal response to *Klebsiella pneumoniae* (National Toxicology Program 2002).

The induction of pulmonary inflammation was examined in three different strains of mice [A/J (sensitive strain for pulmonary inflammation and carcinogenesis), BALB/c (intermediate

sensitivity), and C57Bl/6J (resistant)]. Mice were aspirated with vanadium pentoxide (4 mg/kg) or phosphate-buffered saline, four times per week, with BALF collected at 6 hours, and 1, 3, 6 and 21 days. In A/J mice, vanadium pentoxide increased BALF levels of total cells (95.7%) inflammatory markers (PMNs, macrophages and lymphocytes, 74.6, 99.5, and 623.8%, respectively). Levels of inflammatory chemokines (keratinocyte-derived chemokine, macrophage inflammatory protein-2 and monocyte chemoattractant protein 1), transcription factor activity (NFκB and c-Fos) and signaling pathway activation (MAPK) were increased with highest levels observed in A/J mice followed by BALB/c and then C57BL/6J mice (data in graphs). All results returned to baseline 21 days post exposure (Rondini et al. 2010).

In vitro data with cells or cell lines

No data were located.

Mode of action information

Rondini and colleagues (2010) reported that vanadium pentoxide impacts pulmonary levels of inflammatory markers, induction of chemokines, and modulation of transcription factors Alterations in macrophage mediated functions have been associated with vanadium exposure (Cohen et al. 1996).

The ability of several vanadium compounds to increase mRNA levels of cytokines in BALF was investigated in female CD rats. Rats received 42 or 420 μg of vanadium pentoxide or phosphate- buffered saline by intratracheal instillation. BALF was collected at times ranging from 1 hour to 10 days. Influx of neutrophils was significantly increased 24 hours after exposure to vanadium pentoxide and peaked 24-48 hours post exposure (data in graph). Macrophage inflammatory protein-2 mRNA expression levels were significantly elevated in vanadium pentoxide treated rats at 1 to 48-hour timepoints, as compared to controls (Pierce et al. 1996).

Zinc Dimethyldithiocarbamate (ZDMDC) [CASRN 137-30-4]

Human Data

Data from epidemiology studies

No data were located.

In vitro data with cells or cell lines

ZDMDC induced cytotoxicity in purified NK cells from healthy donors. Exposure to 2.5 μM ZDMDC for 24 hours produced a 99% decrease in lytic function (against K562 target cells) and at 1 μM for 6 days produced a 96% decrease. When a preparation containing T- and NK-cells were exposed to 2.5 μM for 24 hours a 41% decrease in function was observed. Comparatively, a 6-day exposure to 1 μM ziram did not inhibit lytic function. (Whalen et al. 2003). Wilson and colleagues showed that concentrations as low as 125 nM decreased cytotoxic function of purified NK cells (Wilson et al. 2004).

ZDMDC significantly inhibited NK-92MI activity (against K562 target cells) in a dose- and concentration-dependent manner (LOAEL = 0.125 μM at 2 hours incubation). A similar dose- and concentration-dependent inhibition of NK activity was observed with human lymphokine activated killer cells (LOAEL = 0.125 μM at 2 hours incubation) (Li et al. 2012a).

Purified, human NK cells were exposed to ZDMDC (0.5-5 μM) for 1 hour. Then the cells were incubated for 24 or 48 hours, or 6 days in ZDMDC-free media. A decrease in NK activity was observed at 2.5 and 5 μM. The loss of activity lasted up to 6 days after exposure (Taylor et al. 2005).

ZDMDC (5 μg/mL) decreased LPS-induced TNF-α production in THP-1 cells (data in graph). ZDMDC (5 μg/mL) also blocked LPS-induced degradation of I□B (data in Western blot) (Corsini et al. 2006).

ZDMDC induced apoptosis and necrosis in U937, NK-92MI, NK-92CI, Jurkat, and human T cells. Of U937 cells treated with 2 μM ZDMDC, 49.3% were apoptotic and 18.5% were necrotic (Li et al. 2011). In Jurkat cells treated with 0.5 μM ZDMDC, 52.5% were apoptotic and 7.9% were late apoptotic/necrotic (Li et al. 2012c). In NK-92MI cells treated with 0.5 μM ZDMDC, 47.4% were apoptotic and 12.2% were late

apoptotic/necrotic (Li et al. 2012b). In NK-92CI cells treated with 0.5 μM ZDMDC, 28.7% were apoptotic and 38.5% were necrotic (Li et al. 2014).

Increased apoptosis and late apoptosis/necrosis also was observed in a time- and dose-dependent manner in isolated primary T-cells (data in graph) (Li et al. 2012c).

At concentrations ranging from 0.1 to 10 μg/mL, ZDMDC was not cytotoxic to lymphocyte cultures obtained from peripheral blood from healthy volunteers (Zenzen et al. 2001).

Mode of action information

Effects in U937, NK-92MI, and Jurkat cells were dose- and time-dependent. Increased DNA fragmentation, level of active caspase-3, and level of cytochrome c release from U937 and Jurkat

cells also were noted after ZDMDC exposure (Li et al. 2011, 2012c, 2012b, 2015). Increased levels of caspase-7, -8, and -9 also were detected in NK-92MI and Jurkat cells (Li et al. 2012c, 2012b).

ZDMDC-induced inhibition of NK and LAK activity was mediated, in part, by decreases in intracellular levels of Gr3/K, granulysin, perforin, granzyme (Gr) A, and GrB (Li et al. 2012a). Decreased levels of GrB was associated with activation of p38 while activation of p44/42 was associated with decreased levels of perforin (Taylor and Whalen 2011).

Rodent Data

Data from in vivo immunotoxicology or toxicology studies

The EC3 in the local lymph node assay was between 1.0% and 5.0% in female BALB/c mice (De Jong et al. 2002). ZDMDC also was identified as a skin sensitizer in the guinea pig maximization test (TS5 = 0.01%) (van Och et al. 2001).

In vitro data with cells or cell lines

ZDMDC inhibited murine (C57BL/6J) cytotoxic T lymphocyte activity in a dose- and concentration-dependent manner (LOAEL = 0.125 μM) (Li et al. 2012a).

ZDMDC (10 μM) decreased expression of pro-caspase-1 and NLRP3 in J774A.1 cells. Studies in RAW264.7 cells showed that 10 μM ZDMDC increased pro-caspase-1 degradation and not protein cleavage. ZDMDC also decreased LPS-induced production of IL-18 and IL-1ß in bone marrow macrophages. Inhibition of LPS-induced IL-1ß production occurred in a dose-dependent manner in J774A.1 (LOAEL = 5 μM) (Muroi and Tanamoto 2015).

J774A.1 cells were infected with *S. typhimurium* TA98 and then treated with ZDMDC. ZDMDC (1-10 μM) increased the number of infected bacteria in a concentration-dependent manner (LOAEL = 5 μM) (Muroi and Tanamoto 2015).

Mode of action information

ZDMDC increased intracellular level of zinc in rat thymic lymphocytes, which may be associated with induction of apoptosis (Kanemoto-Kataoka et al. 2015).

Final Judgement
no effect

Appendix 11. The summary of the study by the independent biostatistician

1. Results

The concentration-response plot for each experiment is shown in appendix A. We strongly suggest to see the graphs to understand the result of each judgement of experiment.

1.1 Basic results

The judgment of each experiment by chemical is shown in Table 1 for the phase 1 study and Table 2 for the phase II study. Symbols in column “exp.” means “S” for suppression, “A” for augmentation and “N” for no effect. The column “Judge” lists the final judgment of the assay in each laboratory. The column “Chem. Code” is chemical code.

4. Protocol

5. Chemical

6. Records and archiving

7. Study timeline

1. Background

The multicolor reporter assay using IL-2 Luc in Jurkat cells (IL-2 assay) is important for evaluating the immunotoxic potential of chemicals. This assay forms part of the Multi-ImmunoTox assay (MITA) and has the advantages of technical simplicity and a short test period, and the accuracy of the test result is based on the mechanism underlying immunotoxicity.

The aim of this trial is to (pre)validate the IL-2 Luc assay method to assess its transferability and inter-laboratory variability so that this test can be used to screen for immunotoxic chemicals. The IL-2 Luc assay for the validation trial was undertaken i) in accordance with the principles and criteria documented in the OECD No. 34 Guidance Document on the Validation and International Acceptance of New or Updated Test Methods for Hazard Assessment [OECD, 2005], ii) according to the Modular Approach to validation [Hartung et al., 2004], iii) according to the concept discussed in the validation trials with the participation of GLP Test Facilities [Cooper-Hannan et al., 1999] where the whole concept of validation trials is described in the context of GLP, and iv) in line with the ISO procedure JRC.I.03.GP.01v.01 (http://ihcpnet.jrc.it/quality-safety/quality-documents/unit-03-ivm/doc/JRC.I.03.GP.01v.01.pdf).

The studies comprising a validation trial should ideally be performed in accordance with GLP [OECD, 1998-2007; FDA, 1999; EPA, 1998a&b; JSQA, 2010; SCC, 2010]. As a minimum, use of standard operating procedures (SOP) and adequate data recording, reporting and record keeping are essential.

A general conceptual framework [Hartung et al., 2004; OECD, 2005] will be used for documenting the entire study to assess the validation status of the test method. This is called a “modular approach” to validation. In this approach, the information needed to support the validity of the method is organized into modules that provide the following information:

Module 1: Test Definition

Module 2: Within-laboratory repeatability and reproducibility

Module 3: Between-laboratory transferability

Module 4: Between-laboratory reproducibility

Module 5: Predictive capacity

Module 6: Applicability domain

Module 7: Performance standards

The modular approach as introduced by Hartung et al. allows the use of datasets from

various data sources and studies. This advantage is used in the following proposal to assess the scientific validity of the IL-2 Luc assay. This IL-2 Luc assay for the validation trial has been performed under GLP principles.

2. Objective of the trial

The validation trial will assess the reliability (reproducibility within and between laboratories) and relevance (predictive capacity) of the IL-2 Luc assay with a challenging set of test substances (test items) for which high quality *in vitro* and *in vivo* data are available.

3. Validation Management Team (VMT)

The VMT encompasses collective expertise with the test, in the underlying science, and the scientific design, management and evaluation of a validation trial.

The VMT, which plays a central role overseeing the conduct of the validation trial, includes:

Table 1. Members for IL-2 Luc assay Validation Management Team

Name	Role and expertise	Affiliation
Trial Coordinator Hajime Kojima	VMT trial coordinator, Chemical supplier and Management of quality control	JaCVAM, NIHS, Japan (JaCVAM representative)
Lead Lab Yutaka Kimura* Setsuya Aiba*	*Developer of this assay Test method, expertise underlying science	Tohoku Univ., Japan
Takashi Omori	Data analysis, biostatistics dossier	Kobe Univ., Japan
International expert members		
EU liaison Emanuela Corcini	Test system expertise, validation expertise, immunotoxicity expertise	Milan Univ., Italy
EU liaison Erwin L. Roggen	Test system expertise, validation expertise, immunotoxicity expertise	3Rs Management and Consulting ApS, Denmark
ICCVAM liaison	Immunotoxicity expertise	NTP/NIEHS, USA

Dori Germolec		
JSIT liaison Tomoaki Inoue	Immunotoxicity expertise	Chugai Pharmaceutical Co., Ltd.

Participating Test Facilities

The laboratories participating in the trial are defined as follow:

Test Facility 1: Hatano Res. Inst., FDSC. Study Director (SD): Kohji Yamakage

Test Facility 2: AIST, Tsukuba SD: Yoshihiro Ohmiya

Test Facility 3: AIST, Takamatsu SD: Yoshihiro Nakajima

Information relevant for Modules 1, 2, 3 performed by all laboratories. Data obtained by these laboratories have demonstrated that the IL-2 Luc assay is transferable and reproducible between experienced laboratories. All laboratories participating in this validation trial will act as unexperienced laboratories to assess between-laboratory transferability, reliability, and relevance of the IL-2 Luc assay method under non-GLP conditions (GLP principle).

Trial management structure

1) Chemical management group

The members of the chemical management group are elected by recommendation of the IL-2 Luc assay VMT. The members prepare a tentative list of test chemicals and work with the VMT to make a final decision on the test chemicals to be used in the validation trial. The coded test chemicals listed in Table 6 and 7 are distributed by the JaCVAM.

2) Data analysis group

The members of the data analysis group are elected by recommendation of the IL-2 Luc assay VMT and check and analyze the data obtained in this validation trial from a third-party standpoint. The members also take charge of statistical processing in this validation trial.

3) Quality assurance group

The members of the record management group are elected by recommendation of the IL-2 Luc assay VMT. The members prepare the protocol, the test chemical preparation record forms, blank data sheets, etc., and distribute them to the research laboratories participating in this validation trial. The members also collect completed forms and data sheets after completion of the experiments, and point out omissions or flaws in recording, if any, and request corrections of such errors.

4) Lead laboratory

The lead laboratory representing the test method is responsible for providing the test method protocol and the necessary data recording or calculation templates. The Trial Coordinator must ensure that such data recording or calculation templates have been validated before distribution to the test facilities involved in the validation trial. The lead laboratory is also responsible for providing, if necessary, new versions of the protocols during the entire validation trial. The lead laboratory and the other participating test facilities might be contacted by the VMT regarding technical issues.

Sponsor

The validation trial for assessing the validity of IL-2 Luc assay will be financed by the Ministry of Health, Labour and Welfare (MHLW), Japan.

The lead laboratory will support the IL-2 Luc assay validation trial by assuring that reliability is assessed. At the same time, preliminary results of the test method can be evaluated. For this purpose, Lead laboratory will support:

- financial aspects related to the coordination of a validation trial (e.g. organization of VMT meetings where also the involved test facilities can be invited for technical clarifications to the VMT, the publication of the validation trial results)
- test, reference and control item purchase, coding and distribution to the test facility
- availability of the test systems to the participating laboratories by supporting the lead laboratory with the logistics for delivering the test system to the facility
- independent analysis of data and statistical support (biostatistician) based on the study reports generated
- other costs incurred by the participating laboratories

Trial coordination

Dr. Hajime Kojima was appointed as the Trial Coordinator with well-defined roles and responsibilities to coordinate the trial and to establishment of a VMT by supporting of JaCVAM.

The name and location of the Trial Coordinator should be identified in each individual study plan. For the IL-2 Luc assay validation trial, the Trial Coordinator has direct access to the test item coding.

The Trial Coordinator's responsibilities include:

a) Establishment of/support to lead laboratory, including meeting organization
b) Trial communication and coordination with test facilities
c) Recording of document and data flow between test facilities
d) Assessing and documenting the impact of any amendments and/or deviations from the trial plan and study plans on the quality and integrity of the validation trial
e) Ensuring that the individual study reports are forwarded, in a timely manner, for data and statistical analysis
f) Preparing the trial plan and report, which can be based on the study reports from the lead laboratories and other test facilities involved in the validation trial, and should reflect the overall trial
g) Approval with date and signature of all protocols, Study Plans and Study Reports
h) The communication of the results of the trial into the public domain
The Trial Coordinator's responsibilities include:
a) Establishment/support of the lead laboratory, including meeting organization
b) Trial communication and coordination with the test facilities
c) Recording of documents and data flow between the test facilities
d) Assessing and documenting the impact of any amendments and/or deviations from the trial plan and study plans on the quality and integrity of the validation trial
e) Ensuring that the individual study reports are forwarded, in a timely manner, for data and statistical analysis
f) Preparing the trial plan and report, which can be based on the study reports from the lead laboratory and other test facilities involved in the validation trial, and should reflect the overall trial
g) Approval with date and signature of all protocols, study plans and study reports
h) Communication of the results of the trial to the public domain
The role of the Trial Coordinator (as the formal representative of the VMT and the single contact point with the SDs) is of fundamental importance. The Trial Coordinator is the single critical point of trial control and must ensure clear lines of communication between the involved test facilities in the trial. The communication line of the Trial Coordinator is with the SDs of the different test facilities. The SDs are the single point of contact with the Trial Coordinator (unless otherwise communicated by the participating test facilities) to assure a transparent and recorded documentation flow during the trial. The Trial Coordinator should also ensure that appropriate arrangements have been made for the supply of the test systems, and test, control and reference items, which meet the requirements of the trial, and that there are appropriate

test method protocols (dated signature by the Trial Coordinator and the lead laboratory) and, if appropriate, validated data recording, data analysis, and data reporting sheets for the test method.
It is the responsibility of the Trial Coordinator to approve the study plans sent for approval by the test facilities, and any amendments to the study plan, by dated signature.

Training
The lead laboratory will be responsible for issuing a training agenda to the Trial Coordinator for further distribution to all test facilities, giving details of what training aspects will be covered during the training of the other SDs and study personnel at the lead laboratory. Furthermore, after the training during the Phase 0 study, the lead laboratory will issue to the Trial Coordinator a training report and indicate if critical observations are made by the other test facilities regarding the IL-2 Luc assay protocols. In case any critical observations are made, a new version of the IL-2 Luc assay protocols might need be issued to the other test facilities before initiating the between-laboratory transferability test.

[Module 2] Within-laboratory reproducibility
The within-laboratory reproducibility of all test facilities has been done by an independent biostatistical analysis using 5 coded chemicals under the VMT. The concordance should be equal to or greater than 80% as a tentative acceptance criterion for the Phase I study.

3.7 [Module 3] Between-laboratory transferability
This between-laboratory transferability (Module 3) study is performed in order to assess the successful transfer of the assay to a test facility unexperienced with that particular test method but having knowledge of similar test systems and endpoint detection methods.
Transfer of the IL-2 Luc assay to all test facilities in the Phase 0 study using 5 coded five chemicals was achieved. A few concentrations of each test item were tested in triplicate in 3 independent runs according to the IL-2 Luc assay protocol describing the details of the experimental design.
The 5 test items selected for the Phase I study are coded as A, B, C, D, and E. The facilities will prepare a study according to internal GLP principles. This plan will be submitted to the Trial Coordinator and lead laboratory for approval.

The results of the between-laboratory transferability study will be reviewed before progressing with module 4 in the between-laboratory reproducibility study. If the transferability data do not meet the test acceptance criteria, the Trial Coordinator representing the VMT will try to identify the problems and make corrections where needed. At the end of testing, the test facilities will submit a QC certified copy of the entire study dossier to the Trial Coordinator (study plan adhering to GLP principles, raw data, records and data analysis, study report adhering to GLP principles).

3.8 [Module 4] Between-laboratory reproducibility

Twenty-five coded test items have been selected to confirm the between-laboratory reproducibilities in the Phase I and II studies. Several concentrations of each test item will be tested in triplicate according to the IL-2 Luc assay method protocol describing the details of the experimental design.

At the end of testing, the test facilities will submit a QC certified copy of the entire study dossier to the Trial Coordinator (study plan adhering to GLP principles, raw data, records and data analysis, study report adhering to GLP principles). The concordance for between-laboratory reproducibility should be equal or greater than 80% to meet the acceptance criteria.

[Module 5] Predictive capacity

The necessity for further chemical analysis will be subject to a VMT decision once the data for between-laboratory reproducibility has been assessed. Depending on the statistical analysis, lean design for validation as well as automatisation of the test leading to an increased dataset will be considered.

Protocol

In this validation trial, the protocols ver. 0.08E, Phase I and 0.1E, Phase II will be used. These protocols will be drafted by the lead laboratory and will be finalized by the VMT. The criteria to identify immunotoxicants by the MITA are provisionally fixed in protocol ver. 0.08E prior to the Phase I study. There are 2 temporary criteria to identify imunotoxicants. The VMT adopted these criteria after the Phase I validation study.

A measurement of bioluminescence intensity induced by chemical treatment will be measured by a luminometer (Phelios: ATTO, Cat #:AB-2350) calibrated using stabilized SLG, SLO and SLR enzymes in this validation trial.

Chemicals

5.1 Chemical Selection

Test chemicals have been selected from a chemical repository based on published papers on *in vivo* immunotoxicity.

The applied selection criteria were:

information on mode/site of action

coverage of range of relevant chemical classes and product classes

quality and quantity of reference data (*in vivo* and *in vitro*)

high quality data derived from animals and (if available) also humans

knowledge of interspecies variations (for example: variability with regard to the uptake of chemicals, metabolism, etc.)

coverage of range of toxic effects/potencies

chemicals that do not need metabolic activation

appropriate negative and positive controls

physical and chemical properties (feasibility of use in the experimental set-up as defined by the CAS No.)

single chemical entities or formulations of known high purity

availability

cost

In the first phase of the selection procedure, the chemical management group identified and collected several existing lists of potential chemical sensitizers in order to establish a primary database. These chemicals had originally been compiled by international experts for various purposes, such as reference compounds for validation studies. An extensive literature research was performed by the chemical management group, insuring that the preselected chemicals fulfilled the selection criteria described above. Emphasis was laid on the fact that different potencies (strong, weak and no activity) have been chosen. In addition, it was decided that at least 20% of the total substances to be tested should be negative in order to increase the statistical power of the data analysis.

In the first phase of the IL-2 Luc assay validation trial using data generated at the test facilities, 5 chemicals will be tested 3 times for each test chemical for between-laboratory reproducibility and to confirm transferability. After discussion of the Phase I results, detailed test planning for Phase II will be established. Currently, it is planned that 20 chemicals will be tested in the Phase II trial to establish predictive capacity (Table 2).

Table 2. Outline of test planning at each study in the validation trial.

Study	Chemicals	Test Number	Information obtained
Phase I	5 non- coded	1	Between-lab transferability
Phase I	5 coded	3	Within & between-lab reproducibility
Phase II	20 coded	1	Between-lab reproducibility & predictability

5.2 Chemical Acquisition, Coding and Distribution

The within-laboratory reproducibility (Module 2) and between-laboratory transferability (Module 3) in all test facilities have been assessed with coded chemicals. This IL-2 Luc validation trial plan describes generation of the missing data sets under coded test item. If the results obtained are not highly similar to the previously obtained sets, the VMT must assess if coded chemicals need to be tested in all the test facilities.

Coding will be supervised by the Trial Coordinator, in collaboration with the chemical repository responsible for coding and distribution of the test, reference and control items for the validation trial.

5.3 Handling

Each test facility shall receive through the Trial Coordinator essential information about the test chemicals (physical state, weight or volume of sample, specific density for liquid test chemicals, and storage instructions). Moreover, the SD should receive safety information concerning hazards identification and exposure controls/personal protection.

Records and archiving

At the end of the trial, the IL-2 Luc assay validation trial report is prepared by the Trial Coordinator or the VMT personnel who appointed by the Trial Coordinator. The trial report summarizes the trial goals, procedures, results and conclusions of the validation trial. This represents the whole validation trial, including archiving and, as such, will cover several study reports, as well as reports for test item supply, data management and statistics. The Trial Coordinator oversees the preparation of the trial report. The Trial Coordinator will be representing the VMT discussions responsible for preparation of the scientific conclusions. Signatories to the trial report include the Trial Coordinator, the statistician, and the SDs of the involved test facilities. Although the SDs may not be involved with the preparation of the trial report, their signatures confirm that the trial report is an accurate reflection of the management and study events. The trial report should contain a statement, signed by the Trial Coordinator, commenting on the

accuracy and completeness of the trial report and identifying any significant issues which could have affected the integrity of the trial, including matters of GLP compliance. A QC statement will be included in the trial report, in order to identify what QC monitoring was done and to confirm whether or not the trial report is an accurate reflection of the validation trial data.

Study timeline

An approximate schedule for IL-2 Luc assay validation trial is shown in Table 3. The duration of this validation trial is around 20 months, from May 2016 to December 2017.

Table 3. Schedule of IL-2 Luc assay validation trial

Month	Activity
January 2016	Establish the VMT
	Selection of participating research laboratories
	Deliberation, decision and read-through of draft study plan
	Deliberation and decision of protocol
	Preparation of a tentative list of test chemicals
	Distribution of test chemicals, standard chemicals and positive control chemicals
February,2016	Technical transfer using five known chemicals (non-coded) Start of technical transfer **to know between laboratory transferability**
	Data collection of technical transfer (**Phase 0 study**)
Phase I study	
September 2016	Coding and distribution of five coded test chemicals
September, 2016	Start of Phase I study
December, 2016	End of Phase I study
February, 2017	**2nd VMT Meeting** / Phase I results and planning of Phase II study
Phase II study to know between- and within-laboratory reproducibility	
April, 2017	Coding and distribution of coded test chemicals and positive chemicals
May, 2017	Start of Phase II study using 20 coded test chemicals
August,2017	End of Phase II study
November-December, 2017	**3rd VMT Meeting** /reviewing of Phase II study results
2018	Completed validation report

Appendix 15. The list of proficiency chemicals

The list of proficiency chemicals

No.	Chemical name	CAS No.	T cell targeting	Physical state	Phase
1	Dibutyl phthalate	84-74-2	Yes	Liquid	I
2	Lead(II) acetate trihydrate	6080-56-4	Yes	Solid	I
3	Nickel（II) sulfate hexahydrate	10101-97-0	Yes	Solid	I
4	Benzo(a)pyrene	50-32-8	Yes	Solid	II
5	Diethylstilbestol	56-53-1	Yes	Solid	II
6	Urethane, Ethyl carbamate	51-79-6	Yes	Solid	II
7	Tributyltin chloride	1461-22-9	Yes	Liquid	II
8	2.4-diaminotoluene	95-80-7	NO	Solid	II
9	Acetonitril	75-05-8	NO	Liquid	II
10	Vanadium pentoxide	1314-62-1	NO	Solid	II

Prior to routine use of the test method described in this Annex to Test Guideline 442E, laboratories should demonstrate technical proficiency, using the 10 Proficiency Substances listed in Appendix 15 in compliance with the Good in vitro Method Practices (1). Moreover, test method users should maintain a historical database of data generated with the reactivity checks (see paragraph 15) and with the positive and solvent/vehicle controls (see paragraphs 21-24), and use these data to confirm the reproducibility of the test method in their laboratory is maintained over time.

1. OECD (2017), Draft Guidance document: Good *In Vitro €i0Method Practices (GIVIMP) for the Development and Implementation of In Vitro €i0Methods for Regulatory Use in Human Safety Assessment. Organisation for Economic Cooperation and Development, Paris. Available at: [http://www.oecd.org/env/ehs/testing/OECD%20Draft%20GIVIMP_v05%20-%20clean.pdf].*

Appendix 16. The list of performance standard chemicals

No.	Chemical name	CAS No.	T cell targeting	Physical state	Phase
1	Dexamethasone	50-02-2	Yes	Solid	positive control
2	Cyclosporine	59865-13-3	Yes	Solid	-
3	Indomethacin	53-86-1	Yes	Solid	II
4	Perfluorooctanoic acid	335-67-1	Yes	Solid	II
5	Zinc dimethyldithiocarbamate (DMDTC)	137-30-4	No	Solid	I
6	Mannitol	69-65-8	No	Solid	II

Performance standards (PS) (15) are shown to facilitate the validation of modified in vitro IL-2 luciferase test methods similar to the IL-2 Luc assay and allow for timely amendment of this Test Guideline for their inclusion. Mutual Acceptance of Data (MAD) will only be guaranteed for test methods validated according to the PS, if these test methods have been reviewed and included in this Test Guideline by the OECD.

添付資料１．Appendix Table 1
化学物質の免疫毒性データーベース（Phase I, 5 chemicals and Phase II, 20 chemicals）

Chemical name	Immunotoxicity classification		NTP data					
			In vivo	*Ex vivo*		*In vitro*		Mode of action
	Classification	Rationale	immune sytem organ weight	cytokine production	TDAR	cytokine production	T cell proliferation	
Phase I study								
Dibutyl phthalate	TTC	3), 4)	**A (spleen)**			**S (IL-2, 4, IFN-g)(H) A (IL-1b)(H) x 3 S (IL-1b)**		This compound then is proposed to modulate cytokine secretion from both monocytes/macrophages and T cells.
Hydrocortisone	TTC	1)	**S (thymus) x 2 S (spleen)**		**N**	**S (IFN-a)**		
Lead(II) acetate	TTC	1)	**A(thymus)**		**S N**	**S (IFN-g, IL-1b)(H) A (IL-4)(H)**	**S(H)**	
Nickel(II) sulfate	TTC	1)	**N S (thymus)**		**N**	**A (IL-4, IFN-g)(H) S (IL-2) S (IFN-g)**		
dimethyldithiocarbamate (DMDTC)	NTTC					**S (IL-1b)**	**N(H)**	
Phase II study								
2.4-diaminotoluene	NTTC		**N (spleen) A (spleen)**		**S**	-	-	
Benzo(a)pyrene	TTC	2), 3)		**S(IL-2)**	**S x 5 A**	**A (IL-4)(H) N (IFNγ)(H) N (IL-2)(H) S (IL-2, 4, IFN-g)**	**S (H) x 2 S x 6**	Disruption of T-cell activities has been associated with B(a)P induced immunotoxic effects (Urso et al. 1986).
Cadmium Chloride	TTC	2), 3)	**A (spleen) S (spleen)**	**A (IL-2) N (IFN-γ)**	**S x 4**	**A (IFN-g)(H) S (IL-2, IFN-g) A (IFN-g) S (IL-2) A (IL-2)**	**S**	
Dibromoacetic acid (DBAA)	TTC	1), 4)	**A (spleen) S (thymus) x 2**		**N**	**S (IL-2, 4)**	**S**	Overall, studies suggest that DBAA produces immunotoxic effects through modulation of T-cell mediated cell immunity. T-cell apoptosis, through extrinsic and intrinsic pathways, are proposed to play a role in the mode of action.
Diethylstilbestrol (DES)	TTC	1), 2), 4)	**S (thymus) x 4 A (thymus) x 2 A (spleen)**	**A (IFN-g) x 3**	**S**	**A (IL-1) A (IL-2)**		DES exposure was associated with down-regulation of gene expression in the TCR complex, and the TCR and CD28 signaling pathways.
Diphenylhydantoin	TTC	2), 3), 4)		**A (IL-4) S (IFN-γ, IL-2) S (IL-1α) N (IL-6, 12)**	**S A x 2**	-	-	DPH treatment can lead to a decrease of suppressor T cells
Ethylene Dibromide (EDB)	TTC	1)	**S (thymus) S (spleen) N**		**A**	-	**S**	
Glycidol	NTTC		**N**		**S**	-	-	Studies suggest that glycidol modulates B-cell function, and NK cell and macrophage activities.111 and decreased cytotoxic T cell activity
Indomethacin	TTC	3), 4)	**N A (spleen)**		**S x 3 A x 1**	**A (IL-2)(H) A (IFN-g)(H)**	**A (H) x 4 S A x 3**	indomethacin inhibition of prostaglandin synthesis leads to altered T-cell function,
Isonicotinic Acid Hydrazide (IAH)	TTC	2)	**N x 2**			**S (IL-2)(H) A (IL-2)(H) S (IL-1)(H)**	**S (H) x 3 A (H) x 6 A N**	
Nitrobenzene	Undetermined		**A (spleen) x 3 A (thymus) x 2**		**S N**	-		effects on T-cell function may play a role in increased susceptibility to L. monocytogenes (Burns et al. 1994).
Urethane, Ethyl carbamate	TTC	1)	**S (thymus) x2 S (spleen) x 2 N A (thymus) A (spleen)**	**N (IL-2)**	**S x 2 N**	**N (IL-2, 4, IFN-g)(H) A (IFN-g)(H) S (IFN-g)(H)**	**N x 2**	
Tributyltin Chloride (TBTC)	TTC	1)	**S (thymus) x4 S (spleen) x 3**		**N S**	**A (INF-g)(H) N (IL-2, 4)(H) S (IFN-g)(H)**	**S (H) S x 3**	
Perflouorooctanoic Acid (PFOA)	TTC	1)	**S (thymus) x2 S (spleen) x 2**	**N (IFN-g)**		**S (IL-4)(H) N (IL-2)(H)**	**A (H) S (H) N (H)**	Direct modulation of NF-kB has been implicated in modulation of cytokine production and secretion (Corsini et al. 2012).
Dichloroacetic Acid (DCAA)	TTC	2), 3)	**A(spleen)**	**N (IL-2) A (IFN-γ) x 3 S (IL-4) x 2 S (IL-2)**	**N**	**A (IL-2)(H) A (IL-2, IFN-g)**		T-cell activation was one proposed mode of action for DCAA.
Toluene	NTTC		**N**		**N**		**N**	
Acetonitrile	NTTC		**S(thymus)**		**S S**	-	-	
Mannnitol	NTTC						**N (H)**	
Vanadium Pentoxide	NTTC		**N A (spleen)**			**N**	**N**	
o-Benzyl-p-chlorophenol (BCP)	NTTC		**N**		**N**	-	-

#: The criterion number used to define immunotoxicity						

Chemical name	Immunotoxicity classification		NTP data					
			In vivo	*Ex vivo*		*In vitro*		
	Classification	Rationale	immune sytem organ weight	cytokine production	TDAR	cytokine production	T cell proliferation	Mode of action
Phase I study								
Dibutyl phthalate	TTC	3), 4)	**A (spleen)**			**S (IL-2, 4, IFN-g)(H) A (IL-1b)(H) x 3 S (IL-1b)**		This compound then is proposed to modulate cytokine secretion from both monocytes/macrophages and T cells.
Hydrocortisone	TTC	1)	**S (thymus) x 2 S (spleen)**		**N**	**S (IFN-a)**		
Lead(II) acetate	TTC	1)	**A(thymus)**		**S N**	**S (IFN-g, IL-1b)(H) A (IL-4)(H)**	**S(H)**	
Nickel(II) sulfate	TTC	1)	**N S (thymus)**		**N**	**A (IL-4, IFN-g)(H) S (IL-2) S (IFN-g)**		
dimethyldithiocarbamate (DMDTC)	NTTC					**S (IL-1b)**	**N(H)**	
Phase II study								
2.4-diaminotoluene	NTTC		**N (spleen) A (spleen)**		**S**	-	-	
Benzo(a)pyrene	TTC	2), 3)		**S(IL-2)**	**S x 5 A**	**A (IL-4)(H) N (IFNγ)(H) N (IL-2)(H) S (IL-2, 4, IFN-g)**	**S (H) x 2 S x 6**	Disruption of T-cell activities has been associated with B(a)P induced immunotoxic effects (Urso et al. 1986).
Cadmium Chloride	TTC	2), 3)	**A (spleen) S (spleen)**	**A (IL-2) N (IFN-γ)**	**S x 4**	**A (IFN-g)(H) S (IL-2, IFN-g) A (IFN-g) S (IL-2) A (IL-2)**	**S**	
Dibromoacetic acid (DBAA)	TTC	1), 4)	**A (spleen) S (thymus) x 2**		**N**	**S (IL-2, 4)**	**S**	Overall, studies suggest that DBAA produces immunotoxic effects through modulation of T-cell mediated cell immunity. T-cell apoptosis, through extrinsic and intrinsic pathways, are proposed to play a role in the mode of action.
Diethylstilbestrol (DES)	TTC	1), 2), 4)	**S (thymus) x 4 A (thymus) x 2 A (spleen)**	**A (IFN-g) x 3**	**S**	**A (IL-1) A (IL-2)**		DES exposure was associated with down-regulation of gene expression in the TCR complex, and the TCR and CD28 signaling pathways.
Diphenylhydantoin	TTC	2), 3), 4)		**A (IL-4) S (IFN-γ, IL-2) S (IL-1α) N (IL-6, 12)**	**S A x 2**	-	-	DPH treatment can lead to a decrease of suppressor T cells
Ethylene Dibromide (EDB)	TTC	1)	**S (thymus) S (spleen) N**		**A**	-	**S**	
Glycidol	NTTC		**N**		**S**	-	-	Studies suggest that glycidol modulates B-cell function, and NK cell and macrophage activities.111 and decreased cytotoxic T cell activity
Indomethacin	TTC	3), 4)	**N A (spleen)**		**S x 3 A x 1**	**A (IL-2)(H) A (IFN-g)(H)**	**A (H) x 4 S A x 3**	indomethacin inhibition of prostaglandin synthesis leads to altered T-cell function,
Isonicotinic Acid Hydrazide (IAH)	TTC	2)	**N x 2**			**S (IL-2)(H) A (IL-2)(H) S (IL-1)(H)**	**S (H) x 3 A (H) x 6 A N**	
Nitrobenzene	Undetermined		**A (spleen) x 3 A (thymus) x 2**		**S N**	-		effects on T-cell function may play a role in increased susceptibility to L. monocytogenes (Burns et al. 1994).
Urethane, Ethyl carbamate	TTC	1)	**S (thymus) x2 S (spleen) x 2 N A (thymus) A (spleen)**	**N (IL-2)**	**S x 2 N**	**N (IL-2, 4, IFN-g)(H) A (IFN-g)(H) S (IFN-g)(H)**	**N x 2**	
Tributyltin Chloride (TBTC)	TTC	1)	**S (thymus) x4 S (spleen) x 3**		**N S**	**A (INF-g)(H) N (IL-2, 4)(H) S (IFN-g)(H)**	**S (H) S x 3**	
Perflouorooctanoic Acid (PFOA)	TTC	1)	**S (thymus) x2 S (spleen) x 2**	**N (IFN-g)**		**S (IL-4)(H) N (IL-2)(H)**	**A (H) S (H) N (H)**	Direct modulation of NF-kB has been implicated in modulation of cytokine production and secretion (Corsini et al. 2012).
Dichloroacetic Acid (DCAA)	TTC	2), 3)	**A(spleen)**	**N (IL-2) A (IFN-γ) x 3 S (IL-4) x 2 S (IL-2)**	**N**	**A (IL-2)(H) A (IL-2, IFN-g)**		T-cell activation was one proposed mode of action for DCAA.
Toluene	NTTC		**N**		**N**		**N**	
Acetonitrile	NTTC		**S(thymus)**		**S S**	-	-	
Mannnitol	NTTC						**N (H)**	
Vanadium Pentoxide	NTTC		**N A (spleen)**			**N**	**N**	
o-Benzyl-p-chlorophenol (BCP)	NTTC		**N**		**N**	-	-

PROJECT TITLE

Test guideline for identifying the T cell-mediated immunotoxic potential of chemicals using the IL-2 Luc assay

SUBMITTED BY (Country / European Commission / Secretariat)

Japan

DATE OF SUBMISSION TO THE SECRETARIAT

November 11th, 2019

DETAILS OF LEAD COUNTRY/CONSORTIUM

Country /Organisation:	Japan
Agency/ministry/Other:	Japanese Center for the Validation of Alternative Methods / National Institute of Health Sciences / Ministry of Health, Labour Welfare (MHLW) / Ministry of Economy, Trade and Industry (METI)
Mail Address:	3-25-26, Tonomachi, Kawasaki-ku, Kawasaki 210-9501, Japan
Phone/fax:	TEL& FAX: +81-44-270-6597
Email:	takao.ashikaga@nihs.go.jp and/or h-kojima@nihs.go.jp

PROJECT OUTCOMES

☒ New Test Guideline	☐ Guidance document
☐ Revised Test Guideline	☐ Detailed Review Paper
☐ Deletion of an existing Test Guideline	☐ Other, please specify below

MAIN OBJECTIVE OF THE PROPOSAL (max. 150 words)

We propose an *in vitro* immunotoxicity test using a stable luciferase reporter cell line that contain IL-2 promoter-driven luciferase. This assay designated as the IL-2 Luc assay is aimed to be a component of Integrated Approaches to Testing and Assessment (IATA*)* to detect immunotoxic potential of chemicals *in vitro.*

PROPOSED WORK PLAN and RESOURCE NEEDS:

1. Draft workplan for development of the proposal, including any need to establish Ad Hoc Expert Group and mode of meetings (face-to-face, teleconference; electronic discussion group). Indicate key milestones, including first and subsequent drafts of documents and timing of meetings.

Dr. Setuya Aiba et al (Tohoku University, Japan) developed the IL-2 Luc assay as a new *in vitro* immunotoxicity testing in addition to the IL-8 Luc assay; OECD Test Guideline (TG) 442Ef for *in vitro* skin sensitisation assay. The IL-2 Luc assay is a cell-based *in vitro* assay (not involving the use of animals) designed to be used in combination with other *in vitro* tests as part of a battery or ITS (will have to be defined) to detect the immunotoxic potential of chemicals *in vitro*. They have also been involved in the development of an adverse outcome pathway (AOP) contains IL-2 suppression as Key Event in the extended Advisory Group on Molecular Screening and Toxicogenomics (EAGMST) (AOP154).

The Japanese Center for the Validation of Alternative Methods (JaCVAM) recently coordinated a validation study to assess the reliability (transferability, within- and between-laboratory reproducibility) and preliminary predictive capacity of the IL-2 Luc assay. The validation report has been submitted to the JaCVAM International peer review panel. The IL-2 Luc assay has undergone independent peer review during 2019 and the peer review finished in June, 2020. Japan has submitted the validation report and peer review report to the OECD secretariat as attachments of the SPSF.

Prior to the development of a Test Guideline, Japan has developed Detailed Review Paper (DRP) for in vitro immunotoxicity testing. Therefore, Japan wish to discuss a draft TG on IL-2 Luc assay as well as DRP in the expert meeting and WNT. In the near future, the DRP and TG on in vitro immunotoxicity will be approved as the OECD documents.

2. Will additional information, including generation or collection of data, be required? If yes, please describe the anticipated process and timelines.

No additional information is submitted.

3. Indicate the estimated overall resource need (time/money) for member country / consortium and Secretariat

Resources for drafting the document will be provided by the National Institute of Health Sciences (NIHS)/JaCVAM. This effort will be coordinated in collaboration with the other International Cooperation on Alternative Test Methods (ICATM) partners (EURL ECVAM, NTP Interagency Centre for the Evaluation of Alternative Toxicological Methods (NICEATM)/US Coordinating Committee on the Validation of Alternative Methods (ICCVAM), Korean Centre for the Validation of Alternative methods (KoCVAM), Brazilian Centre for the Validation of Alternative methods (BraCVAM) and Health Canada).

4. Is this proposal intended to replace an existing Test Guideline or lead to the deletion of an existing Test Guideline?

No expectation to replace or delete any existing TG. The IL-2 Luc assay may also be a partial method designed to be used within a test battery or ITS for assessing the immunotoxic potential of chemicals.

ESSENTIAL INFORMATION

In this section, please provide the information required by the Working Group of National Coordinators of the Test Guidelines Programme to assess the suitability of the project for the workplan of the Test Guidelines Programme

1. What is the existing or expected regulatory need/data requirement that will be met by the proposed outcome of the project? Please provide details below or as an attachment.

This assay is expected to meet some regulatory needs (e.g., ICH S8 and WHO/IPCS guidance on immunotoxicity). Japanese researchers have been involved recently in developing six AOPs for immunotoxicity in the EAGMST, in which two AOPs contain Key Event of IL-2 suppression. Japan is coordinating to develop a DRP on in vitro immunotoxicity, which includes a tiered approach for a testing strategy on immunotoxicity, with International experts who cooperated IL-2 Luc assay. Considering these advances, JaCVAM will continues to support the development of IL-2 Luc assay.

or as attachment No.__

2. How will the work contribute to further international harmonisation of hazard and risk assessment? Please provide details below or as an attachment.

With the REACH legislation (Regulation 1907/2006/EC), the EU also promotes alternative methods for safety testing. In addition, REACH article 25 states that animal testing must be used as a last resort, which encourages the exploitation of useful alternative methods to the absolute maximum.

The ICCVAM, EURL ECVAM and KoCVAM were liaisons to the Validation Management Group. In addition, JaCVAM was represented on the Validation Management Group. The peer review conducted in line with the Memorandum of Cooperation signed by ICATM aiming at reaching harmonised recommendations on the usefulness and limitations of alternative test methods and their potential role in an ITS for regulatory testing purposes in member countries.

or as attachment No.__

3. How will the proposed project address issues and /or endpoints which are of major human health or environmental concerns? If there are existing Test Guidelines or projects in the work plan of the Test Guidelines Programme covering the same endpoint, please refer to these and

describe the added value and usability of the proposed new test method. Please provide details below or as an attachment.

The IL-2 Luc assay is one of the components constituting the Multi-ImmunoTox assay that we have recently developed to detect immunotoxicity of chemicals [1] [2] [3]. The IL-2 Luc assay uses a stable reporter cell line, 2H4 cell, which is derived from Jurkat cells containing stable luciferase green (SLG) regulated by the IL-2 promoter, stable luciferase orange (SLO) regulated by the IFN-γ promoter, and stable luciferase red (SLR) regulated by the G3PDH promoter. Using this cell line, the IL-2 Luc assay identifies the effects of chemicals on the IL-2 promoter activity in 2H4 cells in the presence of the stimulants phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io).

Immune dysregulation may have serious impacts on human health, ranging from reduced resistance to infection and neoplasia to allergic and autoimmune conditions. Pivotal immune elements of these diseases are the development of antigen-specific effector T-helper type (Th) cells, Th1 cells, Th2 cells, Th17 cells, and regulatory T cells (Treg cells) that are associated with clinical features and disease progression. Consequently, identifying the immunotoxicity of chemicals requires clarifying their effects on the development of these T cells (reviewed by [4]). IL-2 exerts pleiotropic actions on CD4+ T cell differentiation via its modulation of cytokine receptor expression. IL-2 promotes Th1 differentiation by inducing IL-12Rb2 (and IL-12Rb1), promotes Th2 differentiation by inducing IL-4Ra, inhibits Th17 differentiation by inhibiting gp130 (and IL-6Ra), and drives Treg differentiation by inducing IL-2Ra. IL-2 also potently represses IL-7Ra, which decreases survival signals that normally promote cell survival and memory cell development [5]. It is therefore assumed that chemicals that affect IL-2 release by T cells could significantly impact immune function. Needless to say, the evaluation of the effects of chemicals on the IL-2 transcription cannot cover the immunotoxicity of all the chemicals and should be used as IAT. However, the transcription of IL-2 by T cells after stimulation with PMA/Io involves the pathways leading the activation of mitogen activated protein kinases (MAPs), mammalian target of rapamycin (mTOR), nuclear factor-κB (NF-κB), and nuclear factor of activated T-cells (NF-AT) (reviewed by [6]). Since these pathways play a crucial role in intracellular signaling utilized by a variety of immune responses other than IL-2 transcription, the IL-2 Luc assay has the potential to cover the immunotoxicity of substantial numbers of chemicals.

In addition, AOP 154 (Inhibition of calcineurin activity leading to impaired T-cell dependent antibody response) indicates the crucial role of optimal IL-2 production in maintaining normal immune response.

4. Will the project have general support from OECD member countries or is the outcome relevant for just one or a few member countries / stakeholders? Provide details of the countries and the rationale for this view below.

☒ Many countries ☐ A few countries ☐ Only for the submitting country

Given the global interest in accurately labelling products for immunotoxic potential without using animals, it is anticipated that the proposed Test Guideline and the RP will have general support from OECD member countries if determined to be scientifically justified by the peer review process.

5. If the Test Guideline is not intended for general use, indicate if the Test Guideline would be intended for:

☐ Specific (limited) applications such as pesticide usage, or

☐ for specific classes of chemicals (e.g. surfactants) rather than for chemicals in general.

6. If the expected outcome of this proposal is a Test Guideline or a Guidance Document, provide information on the intended use, applicability and limitations of the test method.

Since the 2H4 cell line used in the IL-2 Luc assay is derived from Jurkat cells, it is conceivable that this cell line is more resistant to the cytotoxic effects of chemicals than bone marrow cells. Indeed, our study demonstrated that the IL-2 Luc assay cannot evaluate the immunotoxic effects of some immunosuppressive drugs which act by inhibiting DNA synthesis leading to myelotoxicity [1]. Thus, these chemicals in addition to chemicals that need metabolic activation should be outside the applicability domain. To overcome this drawback at present, the IL-2 Luc assay must be combined with assays capable of detecting myelotoxicity, such as *in vitro* myelotoxicity tests [2]. Similar to other *in vitro* test methods, poor insoluble chemicals are not suitable for this assay.

[1] Kimura Y, Fujimura C, Ito Y, Takahashi T, Aiba S: Evaluation of the Multi-ImmunoTox Assay composed of 3 human cytokine reporter cells by examining immunological effects of drugs. Toxicol In Vitro 28: 759-768, 2014.

[2] OECD: OECD Test Gudeline for the Testing of Chemicals No.442E: In Vitro Skin Sensitisation assays addressing the key Event on activation of dendritic cells on the Adverse Outcome pathway for Skin Sensitisation. http://www.oecd-ilibrary.org/environment/oecd-guidelines-for-the-testing-of-chemicals-section-4-health-effects_20745788. 2017.

7. Provide supporting information on the validation status (i.e. relevance and reliability) of the method. Principles for validation of test methods for OECD Test Guidelines are described in Guidance Document 34.

Provide justification and rationale for the test, including data.

If there are no or limited data available to support the reliability and relevance of the proposed test, indicate if validation work is included in the project.

If there is no need for validation, provide a detailed justification.

Experimental data was generated with the IL-2 Luc assay in a JaCVAM-coordinated validation study designed to allow for an assessment of the reliability and preliminary predictive capacity. The experiment part of IL-2 Luc assay validation study completed in Oct. 2018. For the within-laboratory reproducibility, 5 coded chemicals were tested by 3 laboratories and the average within-laboratory reproducibility was 86.7% (13/15). On the other hand, for the inter-laboratory reproducibility, a total of 25 coded chemicals were evaluated and the concordance rate was 80.0% (22/25).

To determine the predictivity of the IL-2 Luc assay, classification chemicals into those that affect T cell function (T cell-targeting chemicals, TTC) and those that do not directly affect T cell function (non-T cell-targeting chemicals, NTTC) was needed. According to the classification, accuracy is 75% (18/24), specificity is 75% (6/8) and sensitivity is 75% (12/16). The PRP concluded the predictive capacity of the test is not sufficient to detect all immunotoxic chemicals if used as a stand-alone test.

Based on the results, the IL-2 Luc assay may be also a partial method designed to be used within a test battery or ITS for assessing the immunotoxic potential of chemicals and therefore it is expected to contribute to the evaluation depending on member countries' regulatory requirements. The peer review is not foreseen to assess the test method's relevance as a stand-alone method.

8. Describe if the test method includes components, equipment or other scientific procedures that are covered (or pending) by Intellectual Property Rights (IPR) (e.g., patents, patent applications, industrial designs and trademarks). Information should be provided on the overall availability of the IPR-protected components including whether they are commercially available or require a Material Transfer Agreement (MTA) or other licensing agreements. In addition, a description of the IPR-covered component/test system should be disclosed. Note that the OECD has developed Guiding Principles on good practices for the availability/distribution of protected elements in OECD Test Guidelines. The test method developer will be requested to fill in and sign the FRAND Terms Licensing Declaration Form annexed to the Guiding Principles.

8.1 Nature of protected elements (e.g. reagent identity, cell line identity, specific process, etc.):

None

8.2 Form of protection (e.g. trademark, patent, etc.):

None

8.3 For users to access protected elements, please tick the relevant box(es):

☒ MTA required ☐ License requirement ☐ No agreement required

If a license or other agreement is foreseen, please note that terms and conditions should comply with FRAND and a signed declaration needs to be submitted if the project gets onto the work plan. See Annex 2 of the OECD Guiding Principles on Good Licensing Practices for Protected Elements in OECD TGs (2019).

8.4 Are you providing the agreement document(s) referred to in 8.3 with the SPSF:

☐ Yes ☒ No If no, what's the reason?

The Material Transfer Agreement (MTA) in line with the conditions of the OECD template is currently under preparation. It will be prepared by the time when this assay is accepted as the OECD TG.

8.5 How and where can users get access to protected elements?

The Standard Operating Procedure (SOP) for the IL-2 Luc assay and 2H4 cells become available when this assay is accepted as the OECD TG. Laboratories that want to perform the test would obtain the 2H4 cell line from GPC Lab. Co. Ltd., Tottori, Japan, upon signing a MTA in line with the conditions of the OECD template. 2H4 cells will be maintained and quality-checked at regular intervals in GPC.

8.6 Has any search for existing patent(s) possibly associated with this test method been performed (e.g. through patent search or Freedom-To-Operate search). If yes, what was the outcome?

Yes, we have performed. But so far, IL-2 Luc assay does not conflict the other patents.

8.7 Does the test method include any Confidential Business Information? No

If yes, which ones?

<u>IMPORTANT NOTE:</u> Should the OECD and Expert Group working on the Test Guideline development discover that the information provided under Item 3 on IP elements be erroneous or be evolving in the course of the project, the project itself might be re-considered, suspended or cancelled.

9 Have Performance Standards been developed? ☒ Yes ☐ No ☐ N/A

ADDITIONAL INFORMATION

In this section please provide further information to allow the Working Group of National Coordinators of the Test Guidelines Programme to assess the suitability of the project for the workplan of the Test Guidelines Programme

1. If the expected outcome of the project proposal is a Test Guideline and is based on existing, regional or international documents such as guidelines, protocols or guidance material, please provide that information here or as an attachment.

We have been exposed to an enomous number of chemicals as environmental contaminants, food additives, and drugs. Some of them can target the immune system resulting in immune dysregulation, which can have serious adverse health consequences, ranging from reduced resistance to infection and neoplasia to allergic and autoimmune conditions. Accordingly, the potential for immunotoxicity, which is defined as the toxicological effects of xenobiotics on the function of the immune system, has raised serious concerns from the public as well as regulatory agencies. On such a ground, World Health Organization published the Guidance for Immunotoxicity Risk Assessment for Chemicals ((WHO)/ & Meeting, 2012). Furthermore, in the OECD TG 443, assessment of potential developmental immunotoxicity was described as a part of reproductive and developmental effects. The ICH guideline (ICH HARMONISED TRIPARTITE GUIDELINE IMMUNOTOXICITY STUDIES FOR HUMAN PHARMACEUTICALS S8) mentions on nonclinical testing approaches to identify compounds which have the potential to be immunotoxic. Currently, the assessment of chemical immunotoxicity relies mainly on animal models and assays that characterize immunosuppression and sensitization. However, animal studies have many drawbacks, such as high cost, ethical concerns, and questionable relevance to risk assessment for humans.

or as attachment No.__

2. If Animal Welfare considerations are addressed in the project proposal, provide details below or as an attachment. Explain if the project is aimed at refining, reducing and/or replacing the use of animals.

If the project is not specifically developed for animal welfare purposes, indicate if the animal welfare considerations have been a component of the project proposal.

Indicate if animal welfare considerations are irrelevant to the project, for example for physico-chemical properties.

The IL-2 Luc assay is an *in vitro* method not involving the use of animals. Its proposed role is to be a part of a screening approach in combination with other *in vitro* tests, with the purpose of reducing the number of animals used, or when regulatory requirements allows also to replace existing *in vivo* tests for immunotoxicity hazard assessment.

or as attachment No.__

3. Provide information on expected or possible resource savings in member countries as a result of this project.

The Test Guideline will contribute to the reduction of animal usage and provide a screening test that is cost efficient to perform.

4. If the expected outcome of the proposed project is a Guidance Document or Detailed Review Paper, will it be directly linked to the development of a particular Test Guideline or a series of Test Guidelines?

☐ Yes, it is the initial step in the development of a new or revision of existing Guidelines.

☐ Yes, additional guidance is needed for the most appropriate selection of the Guidelines on the subject.

☐ No, the guidance is on issues related to testing or the development of Test Guidelines in general.

1. Summary

The IL-1 Luciferase reporter assay (IL-1 Luc assay) was developed as one of three luciferase reporter assays in the Multi-ImmunoTox Assay (MITA), a high-throughput screening system that our group developed to evaluate chemical immunotoxicity. Although our final long-term goal is to officially validate the MITA for within- and between-laboratory reproducibility and predictivity, in this study we conducted a validation of the IL-1 Luc assay as a second step following the IL-2 Luc assay.

In the MITA, we used three stable lines of reporter cells transfected with luciferase genes under control of the IL-2, IFN-γ, IL-8, and IL-1β promoters: 2H4 cells derived from Jurkat cells containing stable luciferase green (SLG) regulated by the IL-2 promoter, stable luciferase orange (SLO) regulated by the IFN-γ promoter, and stable luciferase red (SLR) regulated by the G3PDH promoter; THP-G8 cells derived from THP-1 cells containing SLO regulated by the IL-8 promoter, SLR regulated by the G3PDH promoter; THP-G1b cells derived from THP-1 cells containing SLG regulated by the IL-1β promoter, and SLR regulated by the G3PDH promoter. We selected these four cytokines because IL-2 and IFN-γ are primarily produced by T cells (a type of adaptive immune cells), whereas IL-8 and IL-1β are primarily produced by monocytes and dendritic cells (types of innate immune cells).

Using these three cell lines, the MITA can evaluate the effects of chemicals on the IL-2 and IFN-γ luciferase activity of 2H4 cells stimulated with phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io), and those on the IL-1β and IL-8 luciferase activity of THP-G1b and THP-G8 cells, stimulated by lipopolysaccharide (LPS).

In the validation study of the IL-1 Luc assay, the preliminary test trial (Phase 0) was performed by the participating laboratories following explicit explanations of the Multi-ImmunoTox Assay protocol for THP-G1b ver. 007E by the lead laboratory, Tohoku University. Three laboratories participated in the Phase 0 study of the IL-1 Luc assay using the three open labeled chemicals dapson, diethanolamine and p-nitroaniline, and conducted one set (three experiments) for each chemical. The response patterns for the

three chemicals were similar among the three laboratories. Based on these results, the VMT judged that technical and protocol transfer of the IL-1 Luc assay is acceptable.

In the Phase I study, a total of five coded chemicals were evaluated by three experimental sets based on the Multi-ImmunoTox Assay protocol for THP-G8 ver. 008E made by the lead laboratory, Tohoku University. The within-laboratory reproducibility was 100.0% (15/15). The between-laboratory reproducibility was 100.0% (5/5). The predictivity was 40.0% (6/15).

The Phase II study for between-laboratory reproducibility and predictivity was conducted using a total of 20 coded chemicals (15 immunotoxic chemicals and 5 non-immunotoxic chemicals) and evaluated by one experiment set based on the Multi-ImmunoTox Assay protocol for THP-G1b ver. 009E. The between-laboratory reproducibility was 80% (16/20) and the predictivity was 46.7% (28/60).

In the combined results of the Phase I and II studies, the within-laboratory reproducibility was 100.0% (15/15). The between laboratory reproducibility was 84.0% (21/25). The predictivity was 45.3% (34/75).

Although the within- and between-laboratory reproducibilities could satisfy the acceptance criteria for the validation study, the predictivity was below 80%. As suggested by non-animal tests for skin sensitization, there is a wide consensus that due to the complex mechanisms involved in the human immune system, there is no single non-animal alternative assay that covers the effects of chemicals on the entire immune response. Instead, it is necessary to develop integrated approaches for testing and assessment (IATA) using multiple assays for different aspects of the immune system. Therefore, this low predictability of the IL-1 Luc assay does not necessarily indicate its limited usefulness as an immunotoxicity test.

We have completed an official validation study of the IL-2 Luc assay, in which the immunotoxicity of chemicals was evaluated by their effects on IL-2 promoter-driven luciferase activity of 2H4 cells. To clarify the characteristics of the IL-1 Luc assay, the lead laboratory examined data for 60 chemicals previously evaluated by the IL-2 Luc assay and two new chemicals added for this study for evaluation by the IL-1 Luc assay.

Although the performance of the IL-1 Luc assay alone was 52.1% for sensitivity, 35.7% for specificity, and 46.7% for predictivity, the performance of the IL-2 Luc assay improved from 77.8% to 83.3% for sensitivity and from 82.5% to 83.3% for predictability when combined with the IL-1 Luc assay. These data indicate the potential usefulness of the IL-1 Luc assay as a component of the IATA for immunotoxicity.

Moreover, by comparing the signaling pathway to induce IL-1β mRNA expression after LPS stimulation with the signaling pathway to induce IL-2 mRNA expression after PMA/Io, it became clear that the signaling molecules TLR4, Mal, TRAM, Myd88, IRAK4 and IRAK1/2 are specific to IL-1β mRNA expression after LPS stimulation. Indeed, the activity of the TLR4 inhibitor TAK-242 and the IRAK4 inhibitor PF06650833 was only detected by the IL-1 Luc assay, and not by the IL-2 Luc assay. The IL-1 Luc assay is thus a promising tool for detecting the effects of chemicals on these signaling molecules. IRAK4 is a key signaling node for transducing the responses of the interleukin-1 (IL-1) receptor family (IL-1, IL-18 and IL-33 receptors) and TLRs (except for TLR3), and has recently attracted widespread attention as a therapeutic target for inflammation and tumor diseases.

These data suggest that although the performance of the IL-1 Luc assay is not satisfactory as a stand alone method when used to examine the chemicals used for the validation study and the dataset, it is a promising approach for detecting the immunotoxicity of chemicals towards a certain aspect of the immune response or as a component of the IATA.

2. Objective of study

The objective of the present validation study was to determine the usefulness and limitations of the IL-1 Luc assay as a Multi-ImmunoTox Assay (MITA): specifically, as a non-animal screening method to detect and assess the immunotoxicity of chemicals. The specific objectives of the study were to establish:

1) “Transferability”, i.e., the extent to which a laboratory can adapt and easily implement the IL-1 Luc assay;

2) “Between- or inter-laboratory reproducibility”, i.e., the extent to which results agree among different laboratories;

3) "Within- or intra-laboratory reproducibility", i.e., the extent to which results agree in the same laboratory; and

3) “Predictivity”, i.e., the extent to which the *in vitro* results agree with the known immunological profiles of the chemicals.

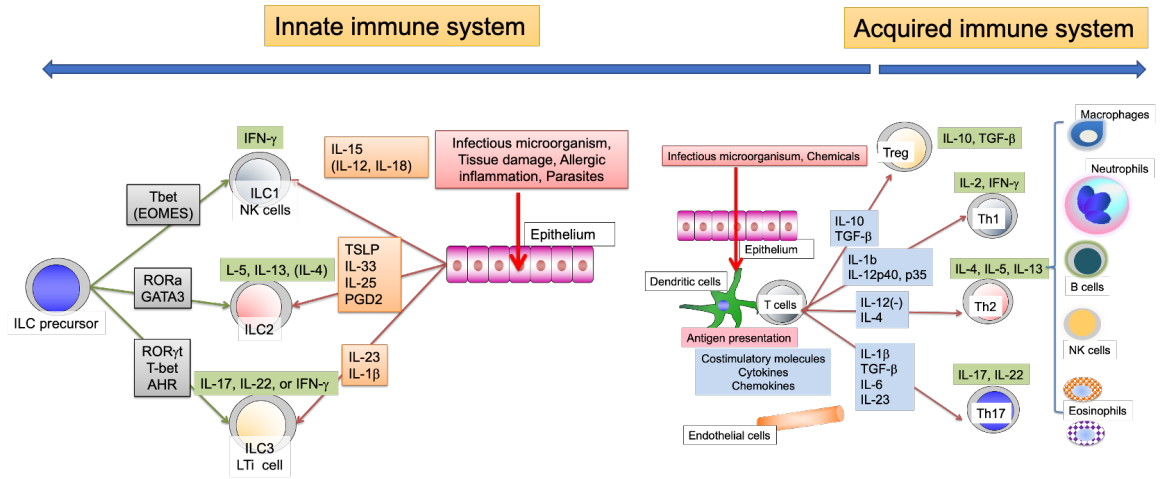
3. Background

3-1. What is immunotoxicity?

A well-functioning immune system is essential for maintaining the integrity of an organism. Immune dysregulation can have serious adverse health consequences, ranging from reduced resistance to infection and neoplasia to allergic and autoimmune conditions. Environmental contaminants, food additives, and drugs can target the immune system, resulting in immune dysregulation. Accordingly, the potential for immunotoxicity, which is defined as the toxicological effects of xenobiotics on the function of the immune system, has raised serious concerns from the public as well as regulatory agencies. Currently, the assessment of chemical immunotoxicity relies mainly on animal models and assays that characterize immunosuppression and sensitization. However, animal studies have many drawbacks, such as high cost, ethical concerns, and questionable relevance to risk assessment for humans. Furthermore, there is global recognition of the need for alternative testing methods and assessment strategies to reduce the use of laboratory animals and, if possible, replace animals used in scientific studies (Adler et al. 2011).

3-2. *In vitro* immunotoxicity tests should evaluate effects on both innate and acquired immunity

The immune system comprises innate and adaptive immunity (Fig. 1). Both arms of the immune response function differently and are driven by different populations of cells. In innate immunity, pathogens are recognized through various pattern recognition molecules, such as C-type lectin receptors, toll-like receptors, nod-like receptors, and retinoic acid–inducible gene-I (RIG-I)-like receptors. In addition, a variety of different cells are involved in this type of response, including neutrophils and other types of granulocytes, macrophages, natural killer (NK) cells, innate lymphoid cells, and mast cells. Adaptive immune responses involve specific antigen receptors encoded by rearranged genes, and T cells and B cells play critical roles in these responses.



2

Fig. 1. Schematic representation of the innate immune system and acquired immune system.

Macrophages and dendritic cells (DCs), which act as antigen-presenting cells (APCs), link the innate and adaptive immune responses because they can present antigens to T lymphocytes in the context of major histocompatibility complex (MHC) class I or II molecules and stimulate their proliferation and effector functions after being stimulated via pathogen recognition receptors (Fig. 2). To induce optimal immune responses to various pathogens and minimize autoreactivity, innate and adaptive

immune cells produce a vast array of cytokines, chemokines, and chemical mediators and present the molecules required for direct cell-cell interaction on their surface. A variety of intracellular signaling pathways also play roles in innate and adaptive immune responses.

Theoretically, chemicals can affect the immune system by targeting either the innate immune system or the acquired immune system (Fig. 1). Therefore, novel *in vitro* test methods are needed to adequately assess the immunotoxic effects of chemicals on both arms of the immune system.

3-3. The current status of *in vitro* approaches to detect immunotoxicants

The workshop hosted by the European Centre for the Validation of Alternative Methods (ECVAM) in 2003 focused on state-of-the-art *in vitro* systems for evaluating immunotoxicity (Galbiati et al. 2010; Gennari et al. 2005; Lankveld et al. 2010). A tiered approach was proposed. Since useful information can be obtained from regular 28-day general toxicity tests, pre-screening for direct immunotoxicity would begin with the evaluation of myelotoxicity in the proposed tiered approach (Corsini and Roggen 2017). Compounds that are capable of damaging or destroying bone marrow will most likely have immunotoxic effects. If compounds are not potentially myelotoxic, they are tested for leukotoxicity. Compounds are then tested for immunotoxicity using various approaches such as the human whole-blood cytokine release assay (HWBCRA), lymphocyte proliferation assay, mixed lymphocyte reaction, NK cell assay, T cell–dependent antibody response, dendritic cell maturation assay, and fluorescent cell chip (FCP) assay. Among these assays, the HWBCRA has undergone formal pre-validation, although other techniques are being examined or have been examined in a rigorous pre-validation effort by the ECVAM and other groups (Fig. 2). However, these assays require fresh rodent or human immune cells, in conflict with animal protection goals. The need for primary cells may decrease reproducibility and makes the assay unsuitable for high-throughput approaches.

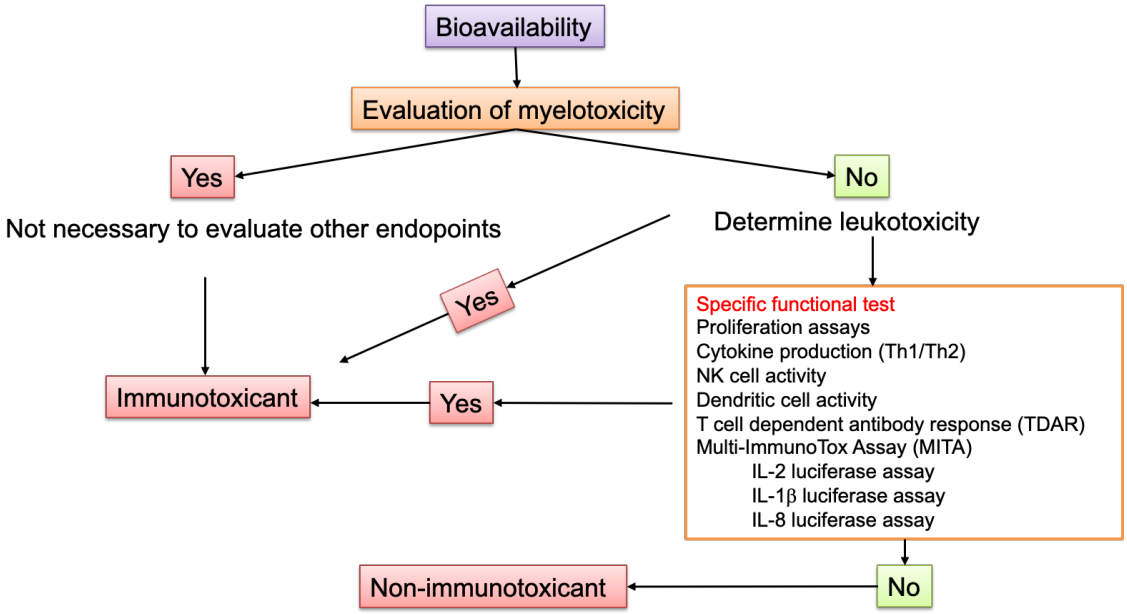


Fig. 2. Decision tree approach for *in vitro* assessment of chemical-induced immunosuppression (modified from Corsini and Roggen. Overview of *in vitro* assessment of immunotoxicity DOI: 10.1016/j.cotox.2017.06.016)

3-4. Further consideration of *in vitro* immunotoxicity tests

Although the above decision tree approach can classify chemicals into those with immunotoxic effects and those without, it seems to be oversimplified. Recent advances in immunosuppressive or immunomodulatory drugs have shown that drugs that affect the immune system can be classified into at least two categories (Isaacs and Burmester 2020; Nelson and Ballow 2003). One comprises immunosuppressants that globally impair the host immune response, typically in a dose-dependent fashion, and are characterized by a low therapeutic index (narrow window between the therapeutic and toxic range) and significant intra- and inter-individual pharmacokinetic variability. The second comprises immunomodulators that act more selectively by targeting only specific portions of the immune system and therefore pose a lower risk of complications related to immune dysfunction, as well as having a wider therapeutic index, a greater safety margin, more predictable pharmacokinetic properties, and less inter-individual variability. The major classes of immunosuppressants are mostly used in transplantation and are classified into glucocorticoids, calcineurin inhibitors such as cyclosporine and tacrolimus, antiproliferative/antimetabolic agents such as azathioprine, mycophnolate

mefetil, sirolimus and everolimus, and biologics such as belatecept, alemtuzumab, muromonab-CD3, daclizumab and basiliximab. On the other hand, the immunomodulators comprise various monoclonal antibodies, such as antibodies against IL-1, IL-4, IL-6, IL-12, IL-17, IL-23 and IL-31.

Taking the classification of the drugs into account, it is reasonable that *in vitro* immunotoxicity tests are also classified as assays to detect chemicals that give global immunosuppression, designated as global immunotoxicity tests, or as assays to detect chemicals that affect a part of the immune response, designated as specific immunotoxicity tests (Fig. 3). The former typically includes myelotoxicity tests, lymphocyte toxicity tests, T cell-dependent antibody response (TDAR), the human whole blood cell cytokine release assay and the IL-2 Luc assay, while the latter includes assays to examine the effects of chemicals on NK cell activity, DC activity, or cytokine or chemokine production.

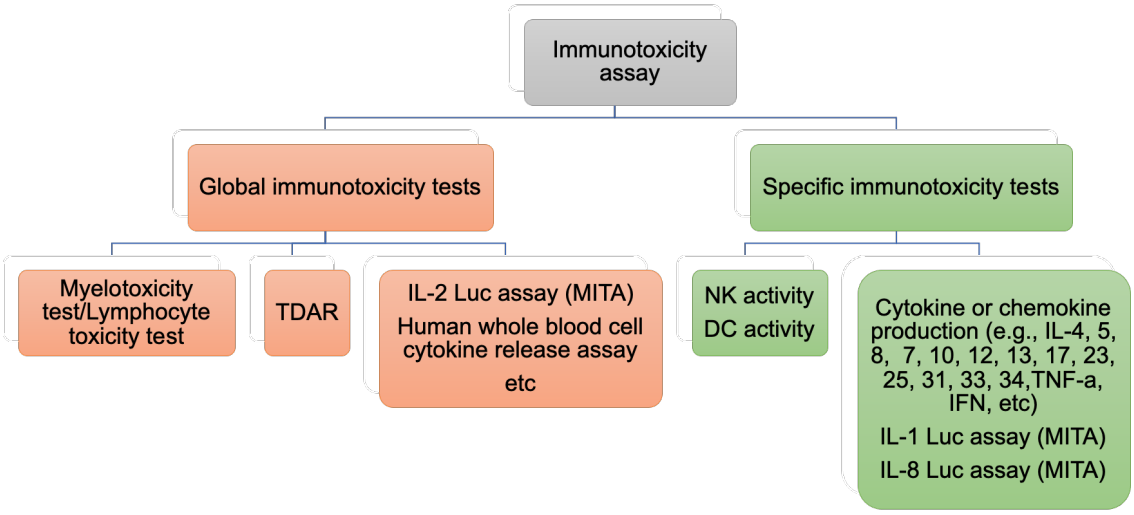

Fig. 3. Classification of immunotoxicity tests in vitro

3-5. Predictivity of *in vitro* immunotoxicity tests

A crucial step in developing an *in vitro* immunotoxicity test involves determining its predictivity. Determining the predictability of tests requires reference data that list the chemicals used to make positive or negative decisions based on results obtained by

gold standard analysis or data obtained from the literature. The reference data for the global immunotoxicity tests and specific immunotoxicity tests should be different.

As suggested by non-animal tests for skin sensitization, determining the predictivity of global immunotoxicity tests cannot be dependent on a single non-animal alternative assay; rather, it is necessary to develop integrated approaches to testing and assessment (IATA) using combinations of assays representing different KEs of the AOP. Moreover, although skin sensitization can be explained by a single AOP, immunotoxicity may be represented by multiple AOPs. Therefore, the predictivity of the *in vitro* test depends on the percentage of chemicals that affect the relevant AOP among the total examined chemicals, making it difficult to determine the goal of predictivity of *in vitro* immunotoxicity tests for global immunotoxicity in the validation study.

3-6. Multi-ImmunoTox Assay (MITA)

Our group developed a high-throughput screening system to evaluate chemical immunotoxicity. We first established three stable reporter cell lines transfected with luciferase genes under control of the IL-2, IFN-γ, IL-8, and IL-1β promoters: 2H4 cells derived from Jurkat cells containing stable luciferase green (SLG) regulated by the IL-2 promoter, stable luciferase orange (SLO) regulated by the IFN-γ promoter, and stable luciferase red (SLR) regulated by the G3PDH promoter (Saito et al. 2011): THP-G8 cells derived from THP-1 cells containing SLO regulated by the IL-8 promoter, SLR regulated by the G3PDH promoter (Takahashi et al. 2011), THP-G1b cells derived from THP-1 cells containing SLG regulated by the IL-1β promoter, and SLR regulated by the G3PDH promoter (Kimura et al. 2014). These four cytokines were selected because IL-2 and IFN-γ are primarily produced by T cells (adaptive immune cells), whereas IL-8 and IL-1β are primarily produced by monocytes and dendritic cells (innate immune cells). Using these three cell lines, we established the Multi-ImmunoTox Assay (MITA). This assay identifies the effects of chemicals on IL-2 luciferase activity (IL2LA) and IFN-γ luciferase activity (IFNLA) in 2H4 cells in the presence of the stimulants phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io), and on IL-1

luciferase activity (IL1LA) and IL-8 luciferase activity (IL8LA) in THP-G1b and THP-G8 cells, respectively, in the presence of the stimulant lipopolysaccharide (LPS) (Fig. 4).

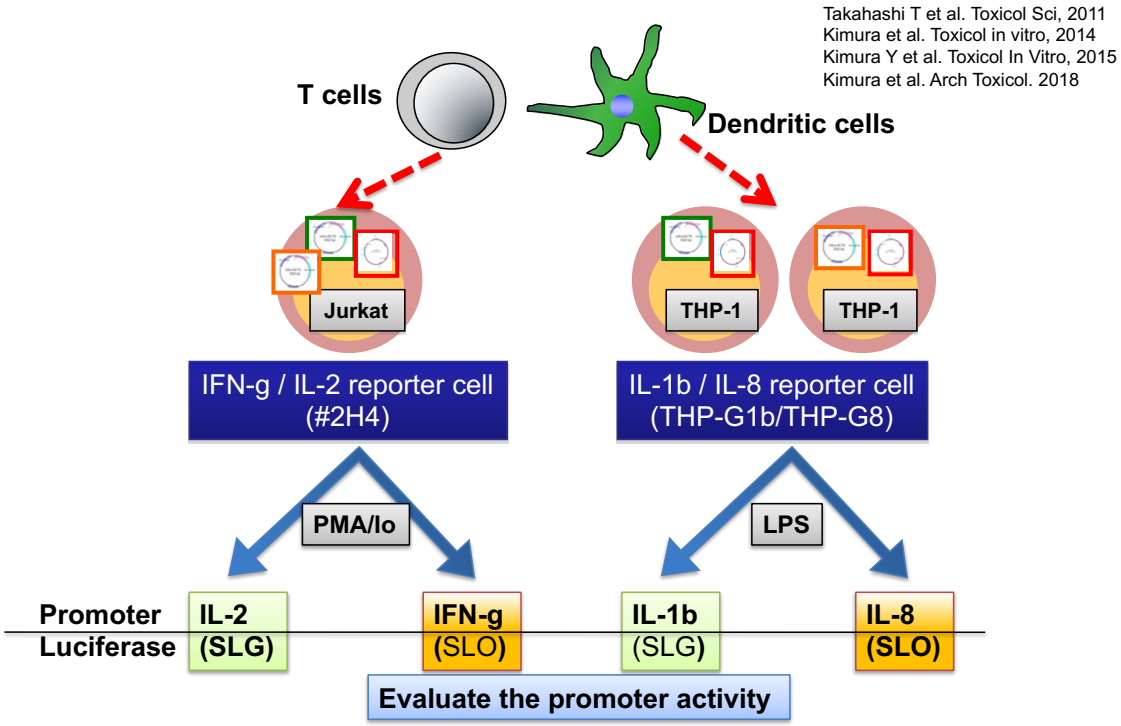

Fig. 4 The Multi-ImmunoTox Assay (MITA)

After establishing the MITA, we first compared the effects of dexamethasone (Dex), cyclosporine (CyA) and tacrolimus (Tac) on the mRNA expression of the three MITA cell lines, and on wild type cell lines or in human whole-blood cells stimulated with PMA/Io or LPS. The results confirmed that the MITA correctly reflects changes in mRNA expression in the mother cell lines and whole-blood cells (Kimura et al. 2014).

3-7. MITA evaluation of immunotoxicity profiles of well-known immunosuppressive drugs

We next evaluated the performance of the MITA by examining immunosuppressive or immunomodulatory drugs with well-known clinical effects on the human immune system (Kimura et al. 2014). The results obtained with

immunosuppressive drugs classified by their principal mechanism of action are shown in Table 1. Drug classifications are based on a review by Allison (Allison 2000).

The MITA demonstrated that Dex significantly suppressed IL-2, IL-1β and IL-8 reporter activity, while CyA and Tac suppressed IL-2 and IFN-γ reporter activity but had no effect on IL-1β and IL-8 reporter activity. However, the MITA could not detect the immunosuppressive effects of the alkylating agent cyclophosphamide, of the inhibitors of *de novo* purine synthesis azathioprine (AZ), mycophenolic acid (MPA) and mizoribine (MZR), or of the inhibitor of pyrimidine and purine synthesis, methotrexate (MT). These data suggest that the MITA correctly evaluates the effects of chemicals on cytokine expression but cannot detect immunotoxicity associated with the inhibition of DNA synthesis and cell division. This drawback has also been reported for other assays, such as the HWBCRA (Langezaal et al. 2002) and the FCP assay (Wagner et al. 2006). On the other hand, the MITA has the advantage that it can discriminate the effects of chemicals on T cells from those on macrophages/dendritic cells.

Table 1. The MITA can detect immunosuppressive effects of representative immunosuppressive drugs

Principal mechanism of action	Drugs	The effects of transcriptional activity			
		IL-2	IFN-γ	IL-1β	IL-8

Kimura et al. Toxicol in Vitro 28: 759-769, 2014

*S and A indicate drugs that showed statistically significant suppression or augmentation in triplicate experiments for each parameter, while N indicates drugs that did not show significant effects.

3-8. Process of validation of MITA and purpose of current validation study

Our final goal is to officially validate the MITA for within- and between-laboratory reproducibility and predictivity. As the initial step, we completed a validation study on the IL-2 Luc assay that evaluated the effects of chemicals on IL2LA in the presence of PMA/Io (Kimura et al. 2020), and the validation report is now under peer review by the OECD. In the current study, we conducted a validation study for the IL-1

Luc assay as the second step. The IL-1 Luc assay is an *in vitro* immunotoxicity test that examines the effects of chemicals on IL1LA in the presence of LPS. Thus, the IL-1 Luc assay is likely to detect chemicals that affect the signaling cascade from TLR4 to the transcription of IL-1β mRNA.

3-9. Significance of assay for detecting effects of chemicals on IL-1β mRNA expression by monocytes

3-9-1. Regulation of IL-1β production

Molecules such as nuclear or mitochondrial DNA, adenosine triphosphate (ATP), uridine triphosphate (UTP), uric acid and high mobility group box 1 (HMGB1) are classified as damage-associated molecular patterns (DAMPs). DAMPs are secreted or produced upon cellular injury or death and induce sterile inflammation. On the other hand, bacterial products like LPS, peptidoglycans, lipoprotein flagellins, and bacterial RNA and DNA are well-characterized pathogen-associated molecular patterns (PAMPs). These DAMPs and PAMPs, with a few exceptions, bind to pattern recognition receptors (PRRs) such as toll-like receptors (TLRs) and nucleotide oligomerization domain (NOD)-like receptors (NLRs). Proinflammatory mediators such as DAMPs, PAMPs and various inflammatory cytokines or mediators, including IL-1β itself, activate innate immune mechanisms in the host, leading to IL-1β production (Handa et al. 2016; Newton and Dixit 2012; Yang et al. 2017).

Transcriptional and post-transcriptional level regulation by the RNA-binding protein pro-IL-1β requires proteolytic cleavage by active caspase-1 as the effector component of stimulation-induced multi-protein inflammasomes to acquire functional activity. These different layers of regulation allow fine tuning of IL-1β production under different pathophysiological conditions (Bent et al. 2018).

3-9-2 Role of IL-1β in pathophysiological conditions

The crucial role of IL-1 has been demonstrated by several experiments using IL-1α- or IL-1β-deficient, both IL-1α- and IL-1β-deficient, or IL-1 receptor 1- (IL-1R1-)

deficient mice. IL-1β is essential for antigen-specific T cell activation and the induction of delayed-type hypersensitivity (Nambu et al. 2006). IL-1α/β deficiency impairs T cell-dependent antibody production through the induction of CD40 ligands and OX40 on T cells (Nakae et al. 2001). IL-1 α/β-deficient or IL-1R-deficient mice have a decreased ability to control infection by *Pseudomonas aeruginosa* (Horino et al. 2009), *Listeria monocytogenes* (Labow et al. 1997), *Leishmania major* (Satoskar et al. 1998), and *Mycobacterium tuberculosis* (Juffermans et al. 2000).

The more precise role of IL-1 in inflammation or immune response has been reviewed (Bent et al. 2018). Briefly, IL-1β is a potent stimulator of antigen-presenting cells (APCs), and can induce maturation of Langerhans cells in the epidermis. IL-1β can also promote the differentiation of monocytes to conventional DCs. IL-1β generated by activated APC induces type 1 immune responses. However, IL-1β also induces IL-4 receptor expression on CD4+ T cells, which is necessary for the maintenance of Th2 cells. In combination with IL-6 and IL-23, IL-1β favors the differentiation of CD4+ T cells towards Th17. On the other hand, IL-1β counteracts TGF-β-induced Foxp3 expression in CD4+ T cells, thereby inhibiting the differentiation of regulatory T cells (Treg). Moreover, IL-1β induces alternative splicing of Foxp3 in Treg, resulting in a functional switch towards Th17. IL-1β not only promotes Th17 polarization via IL1R signaling, but also supports APC-induced Th17 production by CD4+ memory T cells.

IL-1β also supports the proliferation of activated B cells and their differentiation into plasma cells. IL-1β in combination with IL-2 promotes the expansion of NK cells, as well as of CD4+ CD8+ T cells. IL-1β induced in the course of acute inflammation promotes the upregulation of adhesion receptors on immune and endothelial cells as a prerequisite for the infiltration of leukocytes to sites of infection.

In addition to the beneficial role of IL-1β for clearing infections, this cytokine contributes to the severity of several inflammatory diseases and mediates autoinflammatory disorders, such as cryopyrin-associated periodic syndrome, neonatal-onset multisystem inflammatory disease, and familial Mediterranean fever.

3-9-3. Signaling cascade leading to IL-1β mRNA expression after LPS stimulation

The IL-1 Luc assay involves stimulation by LPS, with the binding of LPS to TLR4 and co-receptor MD2 triggering interactions between the cytoplasmic TIR domain of TLR4 and TIR-containing adaptor proteins (Mal, MyD88, and TRAM). MyD88 binds IRAK4, utilizing the kinase activity of IRAK4 to bind the kinases IRAK1 and IRAK2 sequentially. The MyD88–IRAK complex also engages the ubiquitin ligase TRAF6 to generate polyubiquitin chains that activate the IKK complex for NF-κB - and ERK-dependent gene transcription. Ubiquitin ligases cIAP1 and cIAP2 recruited to the TLR4 signaling complex regulate translocation of a subset of signaling components to the cytoplasm, where TAK1 activation initiates a MAPK cascade to activate p38a and JNK, thereby stimulating gene expression. TLR4 activated at the plasma membrane is endocytosed but can signal within the endosomal compartment via the adaptors TRAM and TRIF. The kinase and ubiquitin ligase combination of RIP1 and Peli1 interacts with TRIF to signal NF-κB activation, whereas TBK1 and TRAF3 stimulate IRF3-dependent transcription. These signaling cascades activate nuclear factor-κB (NF-κB), activator protein-1 (AP-1), cAMP responsive element binding protein (CREB)/activating transcription factor (ATF), CCAAT-enhancer-binding protein β *(*c/EBP β) and interferon regulatory factor 3 (IRF3). These transcription factors induce the expression of various inflammatory cytokines, such as IL-1β, TNFα, IL-6, and several chemokines (reviewed by Newton and Dixit (Newton and Dixit 2012)).

On the other hand, the activation of NLRs promotes assembly of inflammasome multiprotein complexes, consisting of NLR family CARD domain-containing proteins, NLRPs, adaptor proteins such as the apoptosis-associated speck-like protein containing a caspase-recruitment domain (ASC), and serine protease caspase 1(Casp1), as well as activing NF-κB (Newton and Dixit 2012). Casp1 is cleaved and activated, further inducing interleukin-1β and IL-18 maturation, which contributes to inflammation.

3-9-4. Suppression of IL-1β production by chemicals

Decreased IL-1 production by macrophages can be induced by suppressed IL-1β

mRNA induction or suppressed maturation of pro-IL-1β, leading to decreased IL-1β secretion. Dexamethasone is a representative drug that significantly suppresses IL-1β production by monocytes (Finch-Arietta and Cochran 1991). As mentioned earlier, the binding of LPS to TLR4 activates the transcription factors NF-kB, CREB/ATF, c/EBPb, AP1 and IRF3. Therefore, chemicals that affect the signaling pathway leading to the activation of these transcription factors are likely to suppress IL-1β production, and chemicals that affect NF-κB signaling have been investigated thoroughly. Numerous compounds have been reported to inhibit NF-κB signaling via several different mechanisms, as reviewed by (Fuchs 2010). A list of representative chemicals and their mechanisms for inhibition of NF-κB is shown in Table 2. Dimethyl fumarate inhibits the activation of NF-κB, resulting in a loss of proinflammatory cytokine production, distorted maturation and function of antigen-presenting cells, and immune deviation of T helper cells (Th) from the type 1 (Th1) and type 17 (Th17) profiles to a type 2 (Th2) phenotype (McGuire et al. 2016; Peng et al. 2012). Several studies have shown intriguing pharmacologic effects associated with curcumin, which inhibits NF-κB expression by regulating the NF-κB/IκB pathway and down-regulating the expression of pro-inflammatory cytokines, such as interleukin (IL)-1, IL-6, IL-8, and tumor necrosis factor (TNF)-α (Wang et al. 2018). Iguratimod, a methanesulfonanilide novel disease-modifying antirheumatic drug, inhibits the nuclear transcription factor NF-κB but not its inhibitor, IκBα (Mucke 2012). Epigaloocatechin gallate (EGCG) has been reported to inhibit NF-κB activation by inhibiting p65 phosphorylation (Wheeler et al. 2004).

Although the binding of LPS to TLR4 activates several transcription factors that can be stimulated by various means other than TLR4 stimulation, there are also signaling molecules that are specific to TLR4 signaling, such as TLR4, Mal, TRAM, Myd88, IRAK4 and IRAK1/2 (Vallabhapurapu and Karin 2009). Several chemicals target some of these molecules, including the TLR4 inhibitor TAK-242 (Matsunaga et al. 2011) and various IRAK4 inhibitors (Lee et al. 2017). IRAK4 has recently attracted widespread attention as a therapeutic target for inflammation and tumor diseases.

Minocycline is orally adsorbed, as are the two prodrugs pralnacasan (VX-740) and belnacasan (VX-765), which are converted into the active compounds VRT-018858 and VRT-043198, respectively (Fenini et al. 2017). All three compounds suppress IL-1 signaling by inhibiting caspase-1 activation. Caspase-1 is an essential enzyme for the maturation of pro-IL-1β and the secretion of mature IL-1β (Vincent and Mohr 2007). It was recently reported that cinnamicaldehyde suppresses serum IL-1β levels in endotoxin poisoned mice (Xu et al. 2017), suggesting that both chemicals and drugs can suppress IL-1 signaling through their inhibitory effects on IL-1β production.

Table 2. List of compounds that inhibit NF-κB signaling (modified from Fuchs 2010)

Target and Function	Compound
AKT/NF-κB inhibitor	AT514 (a cyclic depsipeptide), Xanthohumol
Antiinflammatory and prostaglandin synthase inhibition	Etodolac (SDX-101)
Caspase activation, poly (ADP-ribose) polymerase cleavage and apoptosis	SDX-308 (CEP-180802)
IκB kinase inhibitor	BMS-345541, MLN120B (b-carboline derivative), PS-1145 (b-carboline derivative)
IκB kinase inhibitor, inhibitor of NF-κB expression on both, the protein and mRNA level	Celastrol
IKKβ inhibitor, inhibitor of NF-κB nuclear translocation and induction of apoptosis	AS602868 (anilino-pyrimidine derivative)
IKKα inhibitor	Flavopiridol
Inhibition of RelA binding to DNA	LC-1 (dimethylaminoparthenolide, DMAPT)
Inhibitor of both canonical and non-canonical NF-κB activating pathways at the level of nuclear translocation	DHMEQ
Inhibitor of NF-κB activation, induces G1/S arrest and induces apoptosis	Curcumin
Inhibitor of NF-κB binding to DNA	Epicatechin
Inhibitor of p50 binding to DNA	Kamebakaurin
Mitochondrial dysfunction and apoptosis	Bay117082
NF-κB nuclear translocation inhibitor	SN50 (cell-permeable inhibitor peptide)
Proteasome inhibition, stabilization of IκB	Bortezomib, Carfilzomib (PR-171), CEP-18770
Proteasome inhibition, stabilization of IκB, mitochondrial dysfunction and apoptosis	MG132 (peptidyl aldehyde of tri-leucine), Salinosporamide A (NPI-0052 or ML858)
Reduction of IκBα mRNA levels and decrease in phosphorylated IκBα	4-hydroxy-2-nonenal
ROS generation,caspase activation and apoptosis	Triptolide
Upregulation of A20, downregulation of IKKa and inhibition of p65 nuclear translocation	Berbamine

4. Test method and modification

4-1. IL-1 reporter cell line THP-G1b

A THP-1-derived IL-1β reporter cell line, THP-G1b, harbors the SLG and SLR luciferase genes under the control of the IL-1β and G3PDH promoters, respectively, and was established by the Department of Dermatology, Tohoku University School of Medicine, and GPC Laboratory Co. Ltd. (Kimura et al. 2018). To establish this line, we used THP-1 cells containing stable luciferase red (SLR) regulated by the G3PDH promoter. The IL-1β reporter cassette containing stable luciferase green (SLG) under the IL-1β promoter was transfected into a gene-loading site of a human artificial chromosome (HAC) vector in CHO cells. We transfected the HAC vector into the THP-1-derived cell line containing SLR regulated by the G3PDH promoter from CHO cells using a microcell-mediated chromosome transfer technique to obtain the THP-G1b cell line (Kimura et al. 2018).

4-2. Chemical treatment of THP-G1b cells and measurement of luciferase activity

Based on a previous report (Kimura et al. 2018), THP-G1b cells (1×10^5 cells/50 μL/well) in a 96-well black-frame and white-well plate were pretreated with different concentrations of individual chemicals for 1 h. Next, THP-G1b cells were stimulated with 100 ng/mL of LPS for 6 h. Two luciferase activities (SLG luciferase activity (SLG-LA) and SLR luciferase activity (SLR-LA)) were simultaneously determined using a microplate-type luminometer with a multi-color detection system (e.g., Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)) and Tripluc Luciferase Assay Reagent (TOYOBO Co., Ltd., Osaka, Japan) according to the manufacturers' instructions. Using these cell lines, we obtained SLG-LA driven by the IL-1β promoter (IL1LA) and SLR-LA driven by G3PDH promoter (GAPLA) in THP-G1b cells. We accounted for the variation in cell number and cell viability after chemical treatment by normalizing the data for IL1LA (nIL1LA) by dividing IL1LA with GAPLA in the THP-G1b cells. In addition, we calculated suppression (%), augmentation (%) and Inh-GAPLA as follows:
Suppression (%) = (1 − (nIL1LA of THP-G1b cells treated with drugs/nIL1LA of non-treated THP-G1b cells)) × 100

Augmentation (%) = ((nIL1LA of THP-G1b cells treated with drugs/nIL1LA of non-treated THP-G1b cells) − 1) × 100
Inh-GAPLA = GAPLA of THP-G1b cells treated with chemicals/GAPLA of untreated THP-G1b cells
Definitions of these terms are provided in Table 3.

Table 3. Definition of the parameters in the IL-1 Luc assay.

Abbreviations	Definition
IL-1 Luc assay	IL-1 luciferase assay
GAPLA	SLR luciferase activity reflecting GAPDH promoter activity
IL1LA	SLG luciferase activity reflecting IL-1 promoter activity of THP-G1b cells
nIL1LA	IL1LA/GAPLA of THP-G1b cells
Suppression (%)	(1 − (nIL1LA of THP-G1b cells treated with drugs/nIL1LA of non-treated THP-G1b cells)) x 100
Augmentation (%)	((nIL1LA of THP-G1b cells treated with drugs/nIL1LA of non-treated THP-G1b cells) − 1) x 100
CV05	The lowest concentration of the chemical at which Inh-GAPLA becomes < 0.05.
Inh-GAPLA	GAPLA of THP-G1b cells treated with chemicals/GAPLA of untreated THP-G1b cells.

4-3. Criteria to determine effects of chemicals on monocyte/dendritic cells

During the validation study, we modified the criteria to determine the effects of chemicals on monocyte/dendritic cells. Considering the criteria used in the IL-1 Luc assay described in Multi-ImmunoTox Assay protocol Ver.011E, we set the acceptance

criteria and criteria for the Phase I study of the IL-1 Luc assay as follows (Multi-ImmunoTox Assay protocol for THP-G1b ver. 008E):

Acceptance criteria
If the fold induction of nIL1LA in LPS wells without chemicals (= (nIL1LA of THP-G1b cells treated with LPS)/(nIL1LA of non-treated THP-G1b cells)) is less than 5, the results obtained from the plate containing the control wells should be rejected.

Criteria
The experiments are repeated until two consistent positive (negative) results or two consistent "no effect results" are obtained. When two consistent results are obtained, the chemicals are judged as the obtained consistent results.
An immunotoxicant is identified by the mean of Suppression (%) and its 95% confidence interval.

In each experiment, when a chemical clears the following three criteria, it is judged as suppressive or stimulatory. Otherwise, it is judged as a 'no effect' chemical.
1. The mean of Suppression (%) is $\geq$ 20 (suppressive) or $\leq$ -20 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.
2. The result shows two or more consecutive statistically significant positive (negative) data points or one statistically significant positive (negative) data point with a trend in which at least three consecutive data points increase (decrease) in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is $\geq$ 0.05.

After the Phase 1 study, the criteria were changed to improve the performance of the assay. The following are the final acceptance criteria and the criteria for judgment accepted by the internal expert members (Multi-ImmunoTox Assay protocol for THP-G1b ver. 009E).

Acceptance criteria

- If fold induction for nIL1LA in LPS wells without chemicals (= (nIL1LA of THP-G1b cells treated with LPS)/(nIL1LA of non-treated THP-G1b cells)) is less than 3, the results obtained from the plate containing the control wells should be rejected.
- If the number of concentrations which satisfy Inh-GAPLA $\geq$ 0.05 is less than 6, the experiment is accepted only when viable wells satisfy the following positive criteria. In this case, the following experiments should be conducted using the concentration described in Section 5-1 of Multi-Immuno Tox Assay protocol for THP-G1b ver. 009E (Appendix 6).

Criteria

The experiments are repeated until two consistent positive results or two consistent "non-suppression" results are obtained. When two consistent results are obtained, the chemical is judged as per the obtained consistent results.

An immunotoxicant is identified by the mean of Suppression (%) and its 95% confidence interval.

In each experiment, when a chemical clears the following four criteria, it is judged as being a suppressant. Otherwise, it is judged as a non-suppressant.

1. Suppression (%) is $\geq$ 25 with statistical significance. The statistical significance is judged when the 95% confidence interval does not include 0.
2. The result shows two or more consecutive statistically significant positive data points or one statistically significant positive data point with a trend in which at least three consecutive data points increase in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is $\geq$ 0.05
4. The results at 2000 μg/mL are excluded.

4-4. Bioluminescence system

In a typical dual-reporter assay, firefly luciferase from *Photinus pyralis* (FLuc) is used as the experimental reporter and *Renilla* luciferase is used as the internal control reporter. This internal control reporter connects to a constitutively expressed promoter, such as a virus promoter (e.g., the herpes simplex virus thymidine kinase promoter, simian virus 40 promoter) or a housekeeping gene promoter (e.g., G3PDH, β-actin). This assay system has been commercialized as the Dual-Luciferase Reporter Assay System by Promega Corporation. In this system, both luciferase activities are measured sequentially from single extracts on the basis of their bioluminescent substrate specificity. Firefly luciferase activity is measured first by adding firefly D-luciferin, then *Renilla* luciferase activity is measured by adding coelenterazine (another name for *Renilla* luciferin), with concomitant quenching of firefly luciferase luminescence. Finally, firefly luciferase activity is normalized by *Renilla* luciferase activity as the promoter activity (Michelini et al. 2014; Nakajima and Ohmiya 2010; Roda et al. 2004).

An alternative chemical test using a cell-based assay requires the analysis of a large number of samples. It is preferable to use an improved assay system whereby gene expression can be monitored simultaneously. In the MITA, therefore, three kinds of beetle luciferases that emit either green, orange or red light with a single bioluminescent substrate, D-luciferin, are used. Multiple promoter activities are conventionally evaluated in a one-step reaction by combined use of a commercially available bioluminescent reagent (Tripluc Luciferase Assay Reagent, TOYOBO) and a microplate luminometer equipped optical filters (Nakajima et al. 2005, 2010).

In the IL-2 Luc assay, the triple-color assay system consists of a green-emitting luciferase (SLG; λmax = 550 nm) (Ohmiya et al. 2000; Nakajima et al. 2005) for monitoring IL-2 promoter activity, an orange-emitting luciferase (SLO; λmax = 580 nm) (Viviani et al. 2001; Nakajima et al. 2005) for monitoring IFN-γ promoter activity, and a red-emitting luciferase (SLR; λmax = 630 nm) (Viviani et al. 1999; Nakajima et al. 2005) for monitoring internal control promoter (G3PDH) activity. The three luciferases emit different colors upon reacting with firefly D-luciferin and their

luminescence is measured simultaneously in a one-step reaction by dividing the emission from the assay mixture, measured using optical filters (Nakajima et al. 2005). First, the total relative light units (F0) are measured in the absence of the filters. Then, the F1 and F2 values of light that passed through the R56 filter (>560-nm long-pass filter) or the R60 filter (>600-nm long-pass filter), respectively, are measured. The three luciferase activities are calculated using the simultaneous equation shown below by substituting the F0, F1 and F2 values. In this equation, G, O and R are the activities of the green-, orange- and red-emitting luciferases, respectively, κG_{R56}, κO_{R56} and κR_{R56} are the transmission coefficients for the green-, orange- and red-emitting luciferases of the R56 filter, respectively, and κG_{R60}, κO_{R60} and κR_{R60} are the transmission coefficients for the green-, orange- and red-emitting luciferases of the R60 filter, respectively. The transmission coefficients are simply estimated using purified recombinant luciferase enzymes (Niwa et al. 2010).

$$\begin{pmatrix} F0 \\ F1 \\ F2 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \kappa G_{O56} & \kappa O_{O56} & \kappa R_{O56} \\ \kappa G_{R60} & \kappa O_{R60} & \kappa R_{R60} \end{pmatrix} \begin{pmatrix} G \\ O \\ R \end{pmatrix}$$

Luminescence activity is measured using a filtered 96-well microplate luminometer (for example, Phelios (ATTO, Tokyo, Japan), Tristan 941 (Berthold, Bad Wildbad, Germany), and the ARVO series (PerkinElmer, Waltham, MA).

5. Validation Management Structure

5-1. Validation Management Team (VMT)

Trial Coordinator:	Hajime Kojima (Japanese Center for the Validation of Alternative Methods (JaCVAM), National Institute of Health Sciences (NIHS), Kawasaki, Japan), VMT trial coordinator, Chemical supplier and Management of quality control
Lead laboratory:	Setsuya Aiba (Tohoku University, Miyagi, Japan), Developer of this assay, Test method, expertise underlying science Yutaka Kimura (Tohoku University, Miyagi, Japan)
International expert members	
EU liaison:	Emanuela Corsini (Milan Univ., Italy), Test system expertise, validation expertise, immunotoxicity expertise Erwin L. Roggen (3Rs Management and Consulting ApS, Denmark), Test system expertise, validation expertise, immunotoxicity expertise
ICCVAM liaison:	Dori Germolec (NTP/NIEHS, USA), Immunotoxicity expertise
JSIT liaison:	Tomoaki Inoue (Chugai Pharmaceutical Co., Ltd.), Immunotoxicity expertise
Data management team:	Takashi Omori (Kobe University, Kobe, Japan), Data analysis, biostatistics dossier
Chemical Selection Committee （CSC）	Setsuya Aiba (Tohoku University) Yutaka Kimura (Tohoku University Hajime Kojima (JaCVAM) Emanuela Corsini (Milan Univ) Erwin L. Roggen (3Rs Management and

	Consulting ApS) Dori Germolec (NTP/NIEHS) Tomoaki Inoue (Chugai Pharmaceutical Co., Ltd.)
Participating Test Facilities	Test Facility 1: Hatano Res. Inst., FDSC only for Phase 0 study, Study Director (SD): Kohji Yamakage Test Facility 2: AIST, Tsukuba, SD: Rie Yasuno Test Facility 3: AIST, Takamatsu, SD: Yoshihiro Nakajima Test Facility 4: Tohoku univ. (Phase I, II), SD: Chizu Fujimura

5-2. Management office

5-3. Meetings held

14/5/2018 (Web meeting)
Subjects: Preparation of IL-1β Luc assay procedure
VMT members: Yasuno, R., Yamakage, K., Watanabe, M., Kobayashi, M., Nakajima, Y., Iwaki, T., Aiba, S., Kimura, Y., Fujimura, C., Omori, T., Mashimo, N., Kojima, H.

28/6/2018 (Web meeting)
Subjects: Preparation of IL-1β Luc assay procedure
VMT members: Yasuno, R., Yamakage, K., Watanabe, M., Kobayashi, M., Nakajima, Y., Iwaki, T., Aiba, S., Kimura, Y., Fujimura, C., Omori, T., Kojima, H.

4-6/10/2018 (Kobe Univ., Kobe, Japan)

4th meeting for the MITA Validation study

Subjects: Result of Pre-Validation study of IL-1β Luc assay and validation plan for the Phase I study.

VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T. Aiba, S., Kimura, Y., Yamakage, K., Watanabe, M., Yasuno, R., Nakajima, Y., Omori, T., Takagi, Y., Mashimo, N., Kado, Y., Kojima, H., Venti, S.

Participating laboratories: Tohoku University (Phase I, II), AIST(Tsukuba), FDSC (Phase 0), AIST(Takamatsu)

7/2/2019 (Web meeting)

Subjects: Result of Phase I study of IL-1β Luc assay and Proposal of the revised positive criteria

VMT members: Yasuno, R., Nakajima, Y., Aiba, S., Kimura, Y., Omori, T., Kojima, H.

5/4/2019 (Web meeting)

Subjects: Result of Phase I study of IL-1β Luc assay and Proposal of the revised positive criteria

VMT members: Aiba, S., Kimura, Y., Omori, T., Takagi, Y., Kojima, H.

26/6/2019 (Web meeting)

Subjects: Result of Phase I study of IL-1β Luc assay and Proposal of the revised positive criteria

VMT members: Corsini, E., Roggen, E., Germolec, D., Inoue, T., Aiba, S., Kimura, Y., Omori, T., Kojima, H.

30-31/1/2020 (National Institute of Health Sciences, Richmond Hotel Premier Musashikosugi, Kawasaki, Japan)

5th meeting for the MITA Validation study

Subjects: Validation results for the IL-1β Luc assay**,** Validation report for the IL-1 Luc assay

VMT members: Corsini, E., Germolec, D., Inoue, T. Aiba, S., Kimura, Y., M., Yasuno, R., Nakajima, Y., Omori, T., Mashimo, N., Okayama, K., Kojima, H., Venti, S.

Participating laboratories: Tohoku University, AIST(Tsukuba), AIST(Takamatsu)

6. Study Design (Appendix 1)

The aim of this phase is to (pre)validate the IL-1 Luc assay method to assess transferability and inter-laboratory variability so that this test can be used to screen for immunotoxic chemicals.

The validation study (Phase I and Phase II trials) was conducted by three laboratories, based on the study design and schedule shown in Tables 4 and 5 and using the test chemicals shown in Tables 6 and 7. The methods were described above in Section 4 and the precise protocol is described later in Section 8.

Table 4. Number of chemicals analyzed in validation study

Studies	Within-Laboratory	Between-laboratories	Predictivity
I	5	5	5
II		20	20
Total	5	25	25

7. Test Chemicals

The selection process for the test chemicals for the IL-1β Luc assay validation study is described below.

In addition, the chemical categories or physical state and chemical properties (e.g., solid, liquid, etc.) are included in the tables of these test chemicals in order to investigate the applicable domain.

Table 5. Breakdown of the IL-1 Luc assay validation study

Study	Number of test compounds	Number of repetitions	Information obtained	Experiment date
Phase 0	5 non-coded	1	Between-lab transferability	July, 2018
Phase I	5 coded	3	Within & between-lab reproducibility	November, 2018
Phase II	20 coded	1	Between-lab reproducibility & predictability	July, 2019

7-1. Basic rules for chemical selection

The selection of test chemicals by the CSC in the VMT was based on published papers on *in vivo* immunotoxicity tests and validation studies for *in vitro* alternative assays on immunotoxicity test methods.

7-1-1. Applied selection criteria

- information on mode/site of action
- coverage of a range of relevant chemical classes and product classes
- quality and quantity of reference data (*in vivo* and *in vitro*)
- high-quality data derived from animal and (if available) human studies
- information on interspecies variations (for example: variability with regard to the uptake of chemicals, metabolism, etc.)
- coverage of a range of toxic effects/potencies
- chemicals that do not require metabolic activation
- appropriate negative and positive controls
- physical and chemical properties (feasibility of use in the experimental set-up as implied by the CAS No.)
- single chemical entities or formulations of known high purity
- availability
- cost

In the first phase of the selection procedure, the CSC identified and collected several existing lists of potential chemical immunotoxicants, such as NTP IMMUNOTOX, and an EPA candidate list. An extensive literature search was performed by the CSC in order to ensure that all the pre-selected chemicals fulfilled the selection criteria described above. In addition, it was decided that at least 20% of the total chemicals to be tested should provide negative results (i.e., not immunotoxic) in order to increase the statistical power of the data analysis.

7-1-2. Chemical acquisition, coding and distribution

Laboratory transferability, and within- and between-laboratory reproducibility and predictivity, in all test facilities were assessed using coded chemicals. Coding was supervised by JaCVAM (Appendixes 2-1 and 2-2), in collaboration with the CSC. The CSC was responsible for coding and distributing the test chemicals, references, and controls for the validation study.

7-1-3. Handling

The chemical master at each test facility received complete information considered essential regarding the test chemicals (physical state, weight or volume of sample, specific density for liquid test chemicals, and storage instructions) by JaCVAM. Moreover, the test facility chemical master stored each chemical under conditions in accordance with the storage instructions and received sealed safety information such as the Material Safety Data Sheet (MSDS) describing hazard identification and exposure control/personal protection for each chemical. The test chemicals were delivered directly to the study director and the study director was not shown the MSDSs. The study director was to refer to the MSDSs only in the event of an accident. If the study director referred to the MSDS, he/she was not to reveal the content of the MSDS to the test facility technicians.

No accidents occurred during the course of the validation study, and all test facilities will return the MSDSs for the test chemicals to JaCVAM in a sealed envelope upon completion of the validation study. All test chemicals will be disposed of in compliance with the rules and regulations of the test facilities upon completion of the validation study.

7-2. Pre-validation study

Transferability of this assay was checked using five non-coded chemicals (2-aminoanthracene, citral, chloroquine diphosphate salt, dexamethasone and methylmercury(II) chloride) (Appendix 3) in four test facilities, including the lead laboratory. These chemicals were selected by the CSC.

7-3. Validation study - Phase I trial

Within- and between-laboratory reproducibility of this assay was checked using five coded chemicals in three test facilities, as shown in Table 6 (Appendix 4). These chemicals were selected by the CSC based on the in-house dataset of the lead

laboratory. The chemicals were coded by JaCVAM as shown in Table 6 and distributed to the test facilities.

Table 6. Chemical code list on the phase I validation trial for IL-1 Luc assay

7-4. Validation study -Phase II trial

Twenty test chemicals were selected by CSC for between-laboratory reproducibility as shown in Table 7 (Appendix 5). The chemicals were coded by JaCVAM as shown in Table 7 and distributed to the test facilities.

Table 7. Chemical code list on the phase II validation trial for IL-1 Luc assay

7-5. Acceptance criteria

The within-laboratory reproducibility for all the test facilities was determined by independent biostatistical analysis using five coded chemicals, under supervision by the VMT. The proportion of concordance should be greater than or equal to 80% to be accepted as tentative acceptance criteria for the Phase I study.

Twenty-five coded test items were selected to confirm the between-laboratory reproducibility in the Phase I and II studies. At the end of the testing, the test facilities submitted a QC certified copy of the whole study dossier to the trial coordinator (study plan in accordance with the principles of GLP, raw data, records and data analysis, study report in accordance with the principles of GLP). The proportion of concordance of between-laboratory reproducibility should be greater than or equal to 80% to be accepted as acceptance criteria.

8. Protocols

8-1. Overview of IL-1 Luc assay

An overview of the IL-1β Luc assay is shown in Fig. 5. In addition, the final protocol for the present test (version 009E) is provided as Appendix 6, 7, and 8 and the procedures are described in detail below.

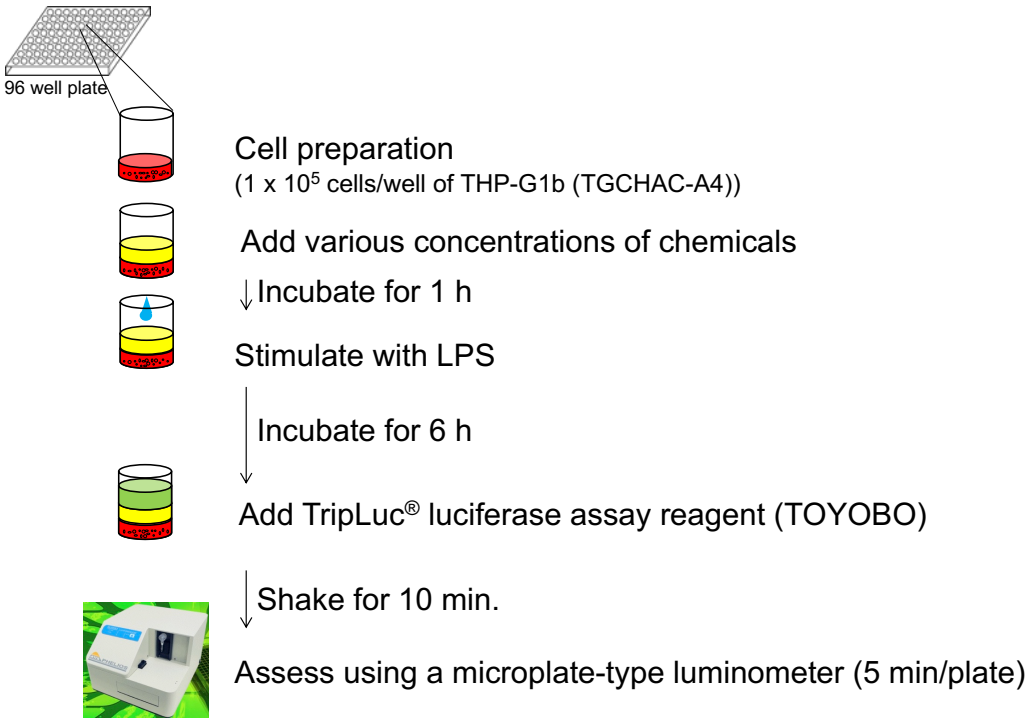

Fig. 5. Overview of the IL-1 Luc assay

8-1 Cells

・/ THP-G1b (TGCHAC-A4) (IL1β-SLG, G3PDH-SLR)

A THP-1-derived IL-1β reporter cell line, THP-G1b (TGCHAC-A4), harbors the SLG and SLR luciferase genes under the control of the IL-1β and G3PDH promoters, respectively, and was established by the Department of Dermatology, Tohoku University School of Medicine, and GPC laboratory Co. Ltd. (Kimura et al. 2018). To establish the THP-G1b cell line, we used THP-1 cells containing stable luciferase red (SLR) regulated by the G3PDH promoter. Then, an IL-1β reporter cassette containing stable luciferase green (SLG) under the IL-1β promoter was transfected into a gene-loading site of a human artificial chromosome (HAC) vector in CHO cells. We transfected the HAC vector into the THP-1-derived cell line containing SLR regulated by the G3PDH promoter from CHO cells using a microcell-mediated chromosome transfer technique to obtain the THP-G1b cell line (Kimura et al. 2018).

8-2. Protocol for IL-1 Luc assay

8-2-1. Reagents and equipment

The following reagents and equipment were used.

For maintenance of the THP-G1b (TGCHAC-A4) cells

- RPMI-1640 (GIBCO Cat#11875-093, 500 mL)
- FBS (Biological Industries Cat#04-001-1E Lot: 715004)
- 100× concentrated antibiotic and antimycotic (10,000 U/mL of penicillin G, 10,000 μg/mL of streptomycin and 25 μg/mL of amphotericin B in 0.85% saline) (e.g., GIBCO Cat#15240-062)

For chemical exposure, stimulation, positive control and solvents

- Lipopolysaccharide (LPS) from *Escherichia coli* K12 (Invivogen Cat#tlrl-eklps, Lot#: LEK-39-01)
- Dexamethasone (CAS:50-02-2, Fujifilm Wako Pure Chemical Cat#041-18861)
- Dimethyl sulfoxide (DMSO) (CAS:67-68-5, Sigma Cat#D5879)
- Distilled water (GIBCO Cat#10977-015)

For measurement of luciferase activity

- Tripluc® Luciferase Assay Reagent (TOYOBO Cat#MRA-301)

Expendable supplies

- T-75 flask, tissue culture treated (e.g., Corning Cat#353136)
- 96-well black-flame and white-well plate (flat-bottom, for measurement of luciferase activity, e.g., PerkinElmer B&W Isoplate-96 TC Cat#6005060)
- 96-well clear plate (round-bottom, for preparation of chemicals and stimulants)
- 96-well assay block, 2 mL (e.g., Costar Cat#3960)
- Seal for 96-well plate (e.g., Perkin Elmer TopSeal-A PLUS Cat#6050185, EXCEL Scientific SealMate Cat#SM-KIT-SP)
- Reservoir
- Pipette

Equipment for measurement of luciferase activity

- Measuring device: a microplate-type luminometer with a multi-color detection system that can accept an optical filter
  e.g., Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)
- Optical filter: a 600 nm long-pass filter or a 600-700 nm band-pass filter

Others

- Pipetman
- 8 channel or 12 channel pipetman (optimized for 10-100 μL)
- Plate shaker (for 96-well plate)
- CO_2 incubator (37°C, 5% CO_2)
- Water bath
- Cell counter: hemocytometer, trypan blue

8-2-2. Culture media

Various culture media were used, depending on the purpose of the cell culture.

Table 8. A medium: for maintenance of THP-G1b cells (500 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO Cat #11875-093	-	-	445 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	50 mL
Antibiotic-Antimycotic	e.g., GIBCO Cat #15240-062	100×	1×	5 mL

Table 9. B medium: for luciferase assay (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO Cat #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10%	3 mL

8-2-3. Preparation of stimulant for THP-G1b cells

Table 10. Lipopolysaccharide (LPS) from *Escherichia coli* K12

Reagent	Company	Concentration of stock solution	Final concentration
Lipopolysaccharide (LPS) from *Escherichia coli* K12	Invivogen Cat#tlrl-eklps	1 mg/mL	100 ng/mL
Distilled water	GIBCO Cat#10977-015		

Dissolve 5 mg LPS using 5 mL distilled water, dispense at 5 μL/tube and store in freezer at -30°C. Use these stocks within 6 months of dissolution.

8-2-4. Thawing of THP-G1b cells

Pre-warm 9 mL of A medium in a 15 mL polypropylene conical tube in a 37°C water bath (for centrifugation) and 15 mL of A medium in a T-75 flask at 37°C in a 5% CO_2 incubator (for culture).

Thaw frozen cells (2×10^6 cells/0.5 mL of freezing medium) in a 37°C water bath, then add to a 15 mL polypropylene conical tube containing 9 mL of pre-warmed A

medium. Centrifuge the tube at 120-350 × *g* at room temperature for 5 min, discard the supernatant, and resuspend the cells in 15 mL of pre-warmed A medium in a T-75 flask. Cells are incubated at 37°C, 5% CO_2.

8-2-4. Maintenance of THP-G1b cells

Three or 4 days after thawing, pre-warm A medium in a T-75 flask at 37°C in a 5% CO_2 incubator. Count the number of cells, centrifuge the tube at 120-350 × *g* at room temperature for 5 min, discard the supernatant, and resuspend the cells in the pre-warmed A medium in a T-75 flask. Cells are passaged at 2-5 × 10^5/mL, depending on the condition of the cells, and incubated at 37°C, 5% CO_2.

The interval between subcultures should be 3-4 days. Cells can be used between 1 and 6 weeks after thawing.

The lead laboratory has examined how long THP-G1b cells can be cultured without losing their reactivity to LPS. THP-G1b cells maintained their response to LPS for up to 16 weeks or 33 passages.

8-2-5. Preparation of cells for assay

Cells should be passaged 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (5.0 × 10^6 cells are required, but to have some leeway, 7.5 × 10^6 cells should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in the pre-warmed B medium at a cell density of 2 × 10^6/mL. Transfer the cell suspension to a reservoir (Thermo Scientific), and add 50 μL of cell suspension to each well of a 96-well black-frame and white-well plate (flat bottom) using an 8 channel or 12 channel pipetman (Gison, Inc., Middleton, WI, USA) (cf. Fig. 6).

Fig. 6. Components in each well of 96-well plates after cell preparation.

8-2-6. Preparation of chemicals and cell treatment with chemicals

Water soluble chemicals were dissolved in distilled water at a concentration of 25 mg/mL. If the chemicals were soluble at 25 mg/mL, then 50 mg/mL solutions were prepared if their solubility was sufficient. If they were not soluble at 50 mg/mL, then 25 mg/mL was judged to be the highest soluble concentration. If the chemicals were soluble at 50 mg/mL, then 100 mg/mL solutions were prepared if their solubility was sufficient. If they were not soluble at 100 mg/mL, then 50 mg/mL was judged to be the highest soluble concentration. If they were soluble at 100 mg/mL, then 100 mg/mL was judged to be the highest soluble concentration.

Chemicals not soluble in water were dissolved in DMSO at 500 mg/mL. If they were not soluble at 500 mg/mL, the highest soluble concentration was determined by diluting the suspension from 500 mg/mL by a factor of 2 with DMSO. Sonication and vortex mixing were used if needed and the attempt to dissolve the chemicals was continued for at least 5 minutes. The dissolution of the chemicals was confirmed by the absence of precipitation after centrifugation at 15,000 rpm for 5 minutes. Dissolved chemicals were used within 4 h after being dissolved in distilled water or DMSO (Fig. 7).

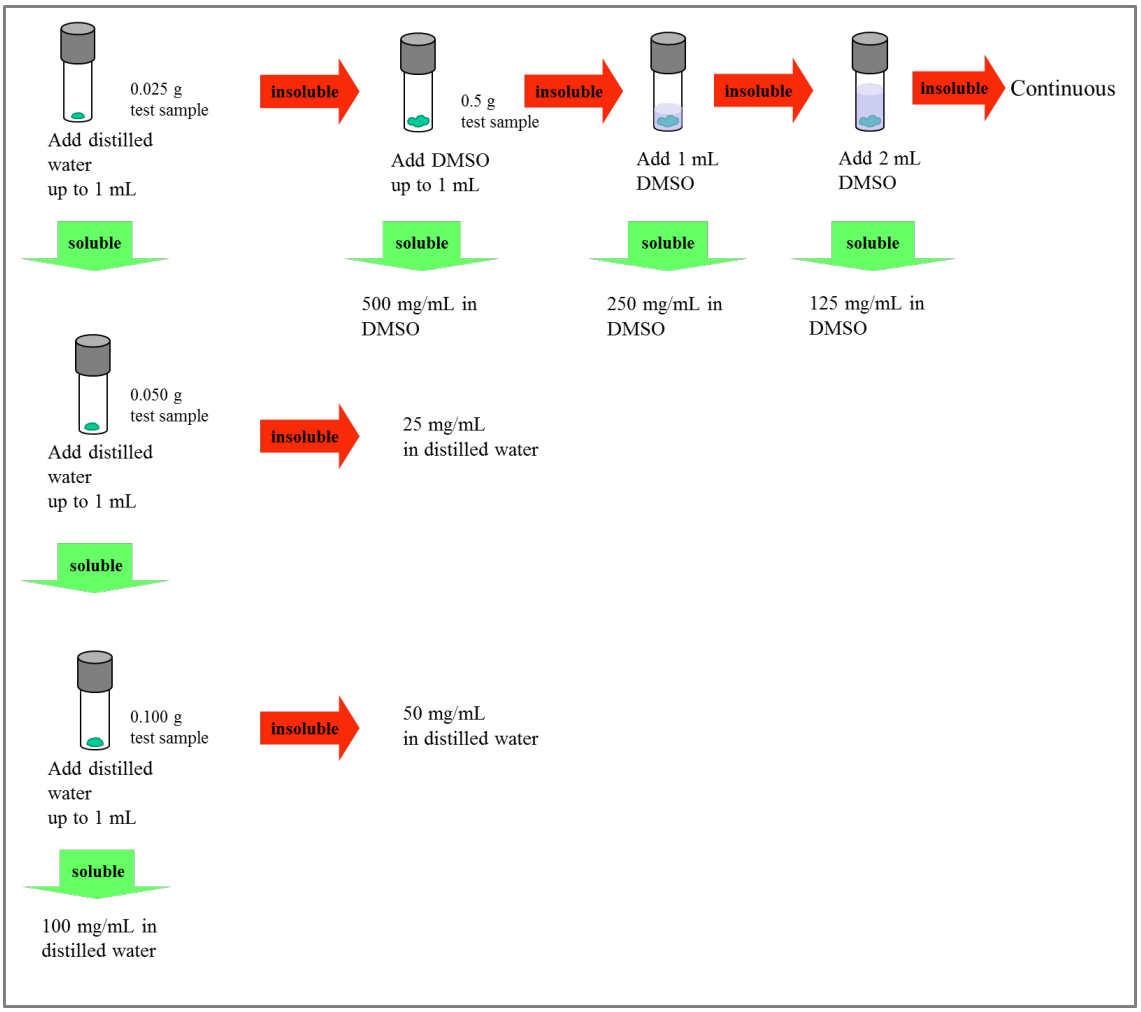

Fig. 7. Dissolution by solvent

8-2-7. Dilution of chemicals

For water soluble chemicals, 11 serial dilutions were conducted using distilled water, diluting by a factor of 2. For water insoluble chemicals, 11 serial dilutions were conducted using DMSO as the solvent, diluting by a factor of 2. The diluted chemicals were added to THP-G1b cells in a 96-well plate. After 1 h incubation at 37°C in a 5% CO_2 incubator, THP-G1b cells were added to 10 μL of LPS solution and incubated again at 37°C in a 5% CO_2 incubator for 6 h.

8-2-8. Measurements

After incubation with the chemical and LPS for 6 h at 37°C in a 5% CO_2 incubator, 100 μL of pre-warmed Tripluc Luciferase Assay Reagent was added to each

well in the plate containing reference samples using a pipetman and the plate was shaken for 10 min at room temperature (about 25°C) using a plate shaker. Surface bubbles were removed if present and bioluminescence from each well was measured using a microplate-type luminometer with a multi-color detection system (Phelios; Atto Co., Tokyo, Japan) for 3 s each in the absence (F0) and presence (F1) of the optical filter. The F0 and F1 data (values are expressed as counts) were processed using an Excel-based data sheet (Appendix 9). IL1LA and GAPLA were calculated for each well based on the algorithm to calculate IL1LA and GAPLA from the raw luminescence data reported previously (Nakajima et al. 2005; Noguchi et al. 2008). In addition to being used to calculate IL1LA and GAPLA, this data sheet can automatically generate final graphs showing the correlation between %suppression and the concentration of the chemical, and between Inh-GAPLA and the concentration of the chemical.

8-2-9. Luminometer apparatus

Multi-color detection systems such as microplate luminometers are available (e.g., Phelios (ATTO, Tokyo, Japan), Tristan 941 (Berthold, Bad Wildbad, Germany), and the ARVO series (PerkinElmer, Waltham, MA)). The luminometer detectors must have high sensitivity (especially for the red region) and low background noise, and are usually equipped with optical filters such as sharp-cut (long-pass) filters or band-pass filters. The transmission coefficients for these filters against each luciferase must be estimated prior to initiating the experiments because the coefficients are dependent on the luminometer due to lot-to-lot variations in detectors.

8-2-10. Positive control

In each experimental set, dexamethasone was used as a positive control.

8-2-11. Calculation and definition of parameters for IL-1 Luc assay

In the IL-1 Luc assay, nIL1LA was defined to represent IL-1β promoter-driven SLG luciferase activity (IL1LA) normalized by the SLR luciferase activity (GAPLA).

The inhibition of GAPLA (Inh-GAPLA) was determined by dividing the GAPLA for THP-G1b treated with chemicals with the GAPLA for non-treated THP-G1b. Percent suppression reflects the effect of chemicals on the IL-1β promoter (Table 11).

Abbreviation	Definition
IL-1 Luc assay	IL-1 luciferase assay
GAPLA	SLR luciferase activity reflecting GAPDH promoter activity
IL1LA	SLG luciferase activity reflecting IL-1 promoter activity of THP-G1b cells
nIL1LA	IL1LA/GAPLA of THP-G1b cells
Suppression (%)	(1 – (nIL1LA of THP-G1b cells treated with drugs/nIL1LA of non-treated THP-G1b cells)) × 100
Augmentation (%)	((nIL1LA of THP-G1b cells treated with drugs/nIL1LA of non-treated THP-G1b cells) – 1) × 100
CV05	The lowest concentration of the chemical at which Inh-GAPLA becomes < 0.05.
Inh-GAPLA	GAPLA for THP-G1b cells treated with chemicals/GAPLA for untreated THP-G1b cells.

Table 11. Abbreviations used in the IL-1 Luc assay protocol

8-2-11 Acceptance criteria (for Phase I study, Multi-ImmunoTox Assay protocol for THP-G1b ver. 008E)

The following acceptance criteria should be satisfied when using the IL-1 Luc assay method.

- If the fold induction of nIL1LA in LPS wells without chemicals (= (nIL1LA for THP-G1b cells treated with LPS)/(nIL1LA for non-treated THP-G1b cells)) is less than 5, the results obtained from the plate containing the control wells should be rejected.

8-2-12 Criteria (for Phase I study, Multi-ImmunoTox Assay protocol for THP-G1b

ver. 008E)

The experiments were repeated until two consistent positive (negative) results or two consistent “no effect results” were obtained. When two consistent results were obtained, the chemicals were judged as the obtained consistent results.

An immunotoxicant was identified by the mean of Suppression (%) and its 95% confidence interval.

In each experiment, when a chemical cleared the following three criteria, it was judged as suppressive or stimulatory. Otherwise, they were judged as ‘no effect’ chemicals.

1. The mean of Suppression (%) is $\geq$ 20 (suppressive) or $\leq$ -20 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.
2. The result shows two or more consecutive statistically significant positive (negative) data points or one statistically significant positive (negative) data point, with a trend in which at least three consecutive data points increase (decrease) in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is $\geq$ 0.05

8-3. Data collection

8-3-1. Operating procedure

Details of the operating procedure for this assay are described in protocol version 008E. Versions of the protocols were updated during the validation studies, but the descriptions of the operating procedures described in these protocols were the same for the two validation studies.

8-3-2. Chemicals

For the Phase I study, in which the main aim was to evaluate intra- and inter-laboratory reliability, a total of 15 coded chemicals were tested in three rounds of five chemicals distributed to three laboratories. Different codes were used in the rounds and thus the technician in each laboratory could not identify the chemicals. For the Phase II study, in which the main aim was to evaluate inter-laboratory reliability, 20 coded chemicals were distributed.

In this document, the chemicals were re-coded. The round is indicated by a suffix such as P101_R1 for the first chemical of the first round of the Phase I study: P1 means Phase I; 01 means the first chemical; _R1 means first round.

Table 12. Chemical codes used throughout this document.

Phase	Chemical code	Lab A	Lab B	Lab C
I	P101_R1, P101_R2, P101_R3, P102_R1, P102_R2, P102_R3, P103_R1, P103_R2, P103_R3, P104_R1, P104_R2, P104_R3, P105_R1, P105_R2, P105_R3	3 rounds	3 rounds	3 rounds
II	P201, P202, P203, P204, P205, P206, P207, P208, P209, P210, P211, P212, P213, P214, P215, P216, P217, P218, P219, P220	1 round	1 round	1 round

8-3-3. Data handling

The Excel data sheet developed for this study was distributed to the laboratories. We received data files from the three laboratories.

From JaCVAM, we received files listing the chemical codes for the five distributed chemicals in the Phase I study, and 20 chemicals in the Phase II study.

For data analysis, these files were combined and datasets were constructed. SAS ver. 9.4 and Microsoft Excel were used for the data analyses described in this report.

Since Excel data sheets can display a concentration-response plot for Suppression (%) with its 95% confidence interval, we could judge “Suppression” or “Negative” visually for each experiment from the plot (Appendix 10 and 11).

8-3-4. Index from each experiment and decision criteria for judgment

The j-th repetition (j = 1 to 4) of the i-th concentration (j = 0 to 11) was measured for IL1LA and GAPLA. The normalized IL1LA is referred as nIL1LA and is defined as $nIL1LA_{ij} = IL1LA_{ij}/GAPLA_{ij}$.

This is the basic unit of measurement in this assay.

8-3-4-1. Suppression (%)

Suppression (%) is an index for the averaged nIL1LA for the repetition using the i-th concentration compared with at 0 concentration and is the primary measure in this assay. Suppression (%) is described by the following formula

$$\text{Suppression}_{\text{i}}(\%) = \left\{1 - \frac{\left(\frac{1}{4}\right)\sum_{\text{i}} \text{nIL1LA}_{\text{ij}}}{\left(\frac{1}{4}\right)nIL1\text{LA}_{0\text{j}}}\right\} \times 100 \qquad (1)$$

The acceptance criteria for a tested chemical was set at 25. This value was based on the results of discussion at the VMT meeting because there are few historical data to help the lead laboratory decide the value for the assay. Before the Phase I study, the data management team prepared three cut-off values (20, 25, and 35) for the acceptance criteria. After the Phase I study, the team presented the results for each cut-off value at the VMT meeting. Based on performance, the VMT decided on 25 as the value and the criteria in the protocol were changed before the Phase II study.

The primary outcome measure, Suppression (%), is basically the ratio of two arithmetic means of nIL1LA, as shown in equation. The 95% confidence interval (95% CI) for Suppression (%) for the i-th concentration can be estimated.

The lower limit of the 95% CI above 0 is interpreted as the nIL1LA of the i-th concentration being statistically significantly greater than at 0 concentration.

There are several ways to construct the 95% CI. We used the method known as the Delta method. This 95% confidence interval is obtained from the following formula

$$\text{Suppression (\%)} \pm 100 \times \left\{ z_{0.975} \times \sqrt{\frac{\text{sd}_\text{i}^2}{\text{mean}_0^2} + \frac{\text{mean}_\text{i}^2 \times \text{sd}_0^2}{\text{mean}_0^4}} \right\},$$

where mean_i is the mean of nIL1LA at the i-th concentration, mean_0 is the mean of nIL1LA at 0 concentration, sd_i is the standard deviation of nIL1LA at the i-th concentration, and sd_0 is the standard deviation of nIL1LA at 0 concentration. $z_{0.975}$ is the 97.5 percentile of the standard normal distribution.

8-3-4-2. Inh-GAPLA

Inh-GAPLA is a ratio of the averaged GAPLA for the repetition of the i-th concentration compared with 0 concentration, and is written as

$$\text{Inh} - \text{GAPLA}_\text{i} = \left(\frac{1}{4}\right) \sum_\text{i} \text{GAPLA}_\text{ij} / \left(\frac{1}{4}\right) \sum_\text{i} \text{GAPLA}_\text{0j}.$$

Since GAPLA is the denominator of the nIL1LA, an extremely small GAPLA value causes a large variation in nIL1LA. Therefore, the i-th Suppression (%) value with an extremely small value of Inh-GAPLA might result in poor precision.

8-3-4-3. Judgment for “Suppression” or “Negative” in each experiment

In each experiment, when a chemical clears the following three criteria, it is judged as being suppressive or stimulatory. Otherwise, it is judged as a ‘no effect’ chemical.

1. The mean of Suppression (%) is ≥ 25 (suppressive) with statistical significance. The statistical significance is judged by its 95% confidence interval.
2. The result shows two or more consecutive statistically significant positive data points or one statistically significant positive data point, with a trend in which at least three

consecutive data points increase in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.

3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is $\geq$ 0.05.

8-3-4-4. Final judgment for "Suppression" or "No effect" using this assay

In this assay, "Suppression" or "No effect" is defined as the case in which there are two identical judgments in a set of experiments.

8-3-5. Reliability

8-3-5-1. Within-laboratory reproducibility for five common chemicals

Within-laboratory reproducibility was determined by whether or not tables of three sets for the final judgment for each chemical by each laboratory were concordant. The concordance rate was then calculated as the proportion of concordance for each laboratory.

The concordance rate for within-laboratory reproducibility was based on the results of three sets.

To summarize, the concordance rate for within-laboratory reproducibility from the three laboratories was used to calculate the averaged concordance rate.

8-3-5-2 Between-laboratory reproducibility

Between-laboratory reproducibility was determined using the results from the final judgment from the three laboratories for 20 chemicals, this is, five chemicals in the Phase I study and 20 chemicals in the Phase II study. These judgements were tabulated, **and** then the concordance rate was calculated as a proportion of the concordance in each laboratory.

To summarize, the concordance rate for between-laboratory reproducibility from the three laboratories was used to calculate the averaged concordance rate.

.

8-3-6. Predictivity

8-3-6-1. Definition of concordance, sensitivity and specificity

In the evaluation of predictivity, we did not distinguish between suppression and stimulation because both indicate modulation of immune function. Rather, we used "Positive (P)" in the case of "suppression" or "stimulation", and "No effect (N)" in the case of no significant effects for each chemical judgement.

The concordance, sensitivity and specificity were estimated as the indices of predictivity. These indices were estimated using the frequency results obtained from the 2 × 2 contingency table for T cell targeting. The definitions of these indices are summarized in Table 13 below. This calculation was based on the results decided by the majority for the between-laboratory results for each chemical.

Table 13. Definition of concordance, sensitivity and specificity

Judgment from IL-1 Luc assay	Chemical category		Total
	Positive	Negative	
Positive	a	b	a+b
Negative	c	d	c+d
Total	a+c	b+d	N

Sensitivity = 100 x a/(a+c)

Specificity = 100 x d/(b+d)

Accuracy = 100 x (a+d)/N

8-3-5. Reliability

8-3-5-1. Within-laboratory reproducibility for five common chemicals

Within-laboratory reproducibility was determined by whether or not tables of three sets for the final judgment for each chemical by each laboratory were concordant. The concordance rate was then calculated as a proportion of the concordance for each laboratory.

The concordance rate for within-laboratory reproducibility was based on the results of three sets.

To summarize, the concordance rate for within-laboratory reproducibility for three laboratories was used to calculate the averaged concordance rate.

8-3-5-2 Between-laboratory reproducibility

Between-laboratory reproducibility was determined using the results from the final judgment from the three laboratories for 25 chemicals, this is, five chemicals in the Phase I study and 20 chemicals in the Phase II study. These judgements were tabulated, and then the concordance rate was calculated as a proportion of the concordance for each laboratory.

To summarize, the concordance rate for between-laboratory reproducibility for the three laboratories was used to calculate the averaged concordance rate.

.

8-3-6. Predictivity

8-3-6-1. Definition of concordance, sensitivity and specificity

In the evaluation of predictivity, we did not distinguish between suppression and stimulation because both indicate modulation of immune function. Rather, we used “Positive (P)” in the case of “suppression” or “stimulation”, and “No effect (N)” in the case of no significant effects for each chemical judgement.

The concordance, sensitivity and specificity were estimated as the indices of predictivity. These indices were estimated using the frequency results obtained from the 2×2 contingency table for T cell targeting. The definitions of these indices are summarized in Table 13. This calculation was based on the results decided by the majority for the between-laboratory results for each chemical.

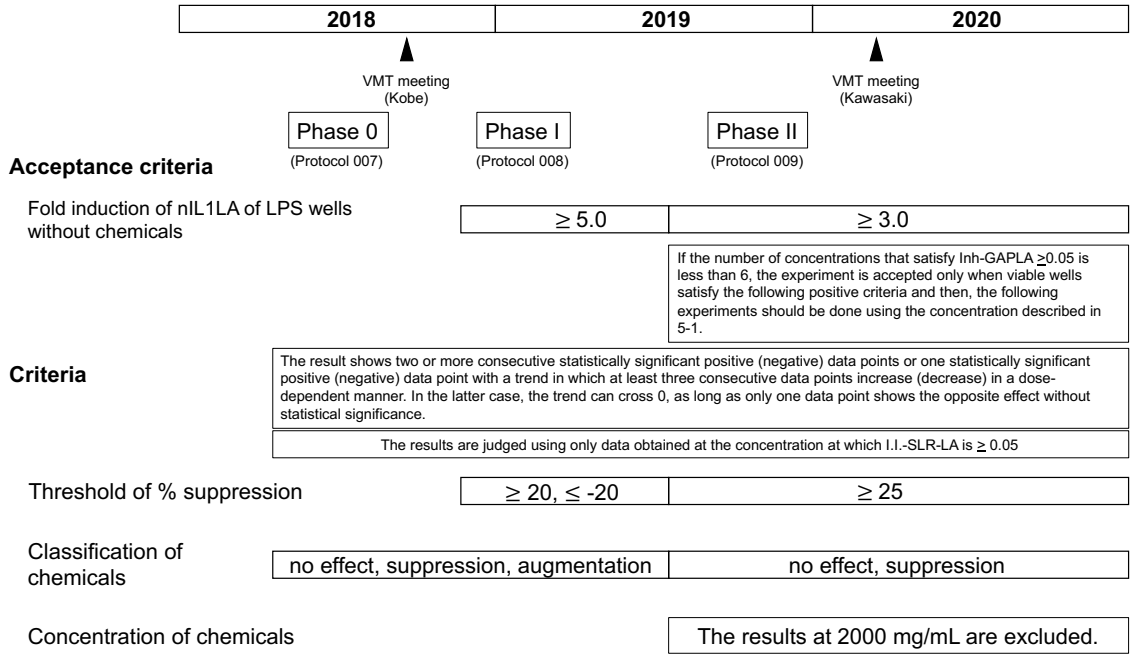
8-4. Quality assurance

Assays and quality assurance were carried out in the spirit of GLP, although not all the participating laboratories routinely worked under GLP certification. The participating laboratories conducted the experiments in accordance with the protocol provided by the VMT. All raw data and data analysis sheets were pre-checked for quality by each laboratory and were then reviewed by the VMT quality assurance team. The results accurately reflected the raw data.

9. Results

We conducted Phase I and II studies in this validation. The assay procedure and criteria used to judge immunotoxicants in the validation studies are summarized in Fig. 8.

Fig. 8. Modification of the protocols of the IL-1 Luc assay.



9-1. Final criteria for Phase I study

9-1-1. Acceptance criteria

The following acceptance criteria should be satisfied when using the MITA method.

Each time an experiment was conducted, a control experiment examining nIL1LA for THP-G1b cells treated with LPS, and nIL1LA for non-treated THP-G1b cells, was conducted. Then, the fold induction for nIL1LA for LPS wells without chemicals (= (nIL1LA for THP-G8 cells treated with LPS)/(nIL1LA for non-treated THP-G1b cells)) was calculated. If the fold induction was less than 5.0, the results obtained from these experiments was rejected.

9-1-2. Criteria

The experiments were repeated until two consistent positive (negative) results or two consistent "no effect results" were obtained. When two consistent results were obtained, the chemicals were judged as the obtained consistent results.

An immunotoxicant was identified by the mean of Suppression (%) and its 95% confidence interval.

In each experiment, when a chemical clears the following three criteria, it is judged as suppressive or stimulatory. Otherwise, it is judged as a 'no effect' chemical.

1. The mean Suppression (%) is $\geq$ 20 (suppressive) or $\leq$ -20 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.
2. The results show two or more consecutive statistically significant positive (negative) data points or one statistically significant positive (negative) data point with a trend in which at least three consecutive data points increase (decrease) in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is $\geq$ 0.05

9-1-3. Predictivity

As already described, there are at least two targets of *in vitro* immunotoxicity tests: global immunosuppression, and limited immune response. In this validation report we

therefore first examined the predictivity of the IL-1 Luc assay as an immunotoxicity test that targets global immunosuppression (global immunotoxicity test), since IL-1β has pleiotropic effects, as described in section 3-9-2. Although reference data that aid positive or negative judgments are essential in determining the predictability of tests, no such reference data are currently available to determine the predictability of the IL-1Luc assay. Thus, we tried to generate reference data for the chemicals used in this validation study of the IL-1 Luc assay. We referred to the rationale for immunotoxic classification proposed by Luster et al. where they presented a screening battery using a 'tier' approach to detect potential immunotoxic compounds in mice (Luster 1998). According to their rationale, a positive reference chemical would either produce a significant dose-response effect in the immune test or significantly alter two or more immune test results at the highest dose of the chemical tested. They classified chemicals based on the results obtained in 12 immune tests according to this rationale and found a significant correlation between the judgment of immunotoxic chemicals and host resistance (Luster et al. 1993). Therefore, using this rationale, we classified chemicals as described in our previous publication. (Kimura et al. 2020).

We first surveyed the literature (Appendix 12 and 13), collected the following eight endpoints regarding each chemical used in the study (Table 14), generated reference data for their immunotoxic profiles, and identified chemicals that satisfy at least one of the following three criteria for immunotoxic chemicals (Table 15). The summarized immunotoxicity information and the classifications of the chemicals are shown in Appendix 14 and 15.

Table 14. Immunotoxicological data obtained from literature.

Endpoint	**Information**
Endpoint 1	Decreased antibody response
Endpoint 2	Suppressed T cell proliferation upon stimulation with innate immune cells, such as dendritic cells or macrophages

Endpoint 3	Decreased LPS response *in vivo*, *ex vivo*, or *in vitro*
Endpoint 4	Suppressed DHR
Endpoint 5	Suppressed host resistance
Endpoint 6	The NTP data or Tox 21 data indicate immunotoxicity of chemicals
Endpoint 7	Increased or decreased mRNA expression or protein production of IL-1β, TNF-α, IL-6, or other proinflammatory cytokines by innate immune cells *ex vivo.*
Endpoint 8	Increased or decreased mRNA expression or protein production of IL-1β, TNF-α, IL-6, or other proinflammatory cytokines by innate immune cells *in vitro.*

Table 15. Criteria to classify immunotoxic chemicals

Criterion	Definition
Criterion 1	Satisfy one of Endpoints 1 to 6
Criterion 2	Increased or decreased mRNA expression or protein production in one or more cytokines in Endpoints 7 or 8 in multiple reports
Criterion 3	Increased or decreased mRNA expression or protein production in two or more cytokines in Endpoints 7 or 8

The predictivity of the IL-1 Luc assay was determined by comparing the results of the IL-1 Luc assay (positive or no effect) with the classification of the chemicals (immunotoxic or not).

9-2. Phase 0 study (for technical transfer)

The preliminary test trial (Phase 0) was performed by the participating laboratories following explicit explanations of the Multi-ImmunTox Assay protocol for THP-G1b ver. 007E by the lead laboratory, Tohoku University. Three laboratories participated in the Phase 0 study of the IL-1 Luc assay using the three open-labeled chemicals dapson, diethanolamine and p-nitroaniline, and conducted one set (three experiments) for each chemical. When the threshold of Suppression (%) was the highest, the response patterns for the three chemicals were similar among the three laboratories. Based on these results, the VMT judged that technical and protocol transfer of the IL-1 Luc assay is acceptable.

9-3. Phase I study (for within- and between-laboratory reproducibility)

9-3-1. Test conditions

A total of five coded chemicals were evaluated by three experimental sets in the Phase I study based on the Multi-ImmunoTox Assay protocol for THP-G8 ver. 008E.

In each experimental set, three or more experiments were conducted for each chemical.

Chemicals that satisfied the criteria were judged as positive. Chemicals that provided two positive results were judged as immunotoxicants.

9-3-2. Within-laboratory variation assessments in Phase I study

Lab A	60.0% (3/5)
Lab B	100.0% (5/5)
Lab C	40.0% (2/5)
Average	66.7% (10/15)

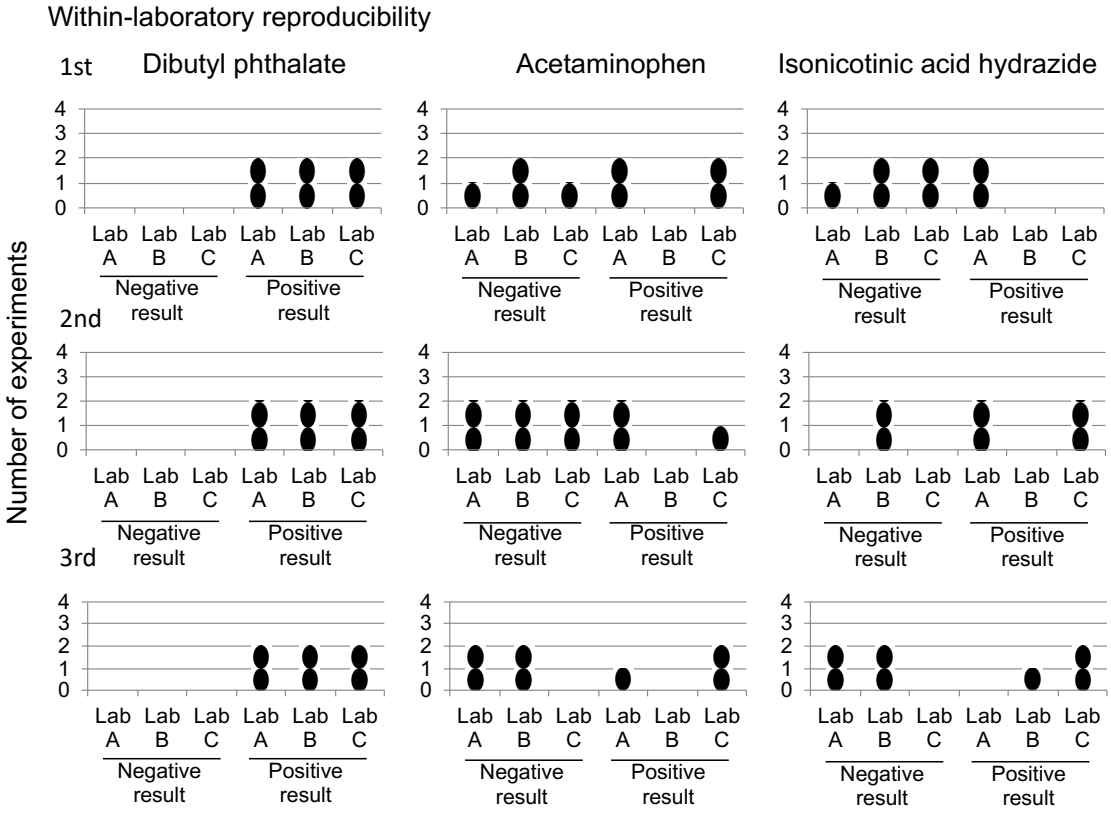
A graphical presentation of between- and within-laboratory variation in the Phase I study is shown in Fig. 9.



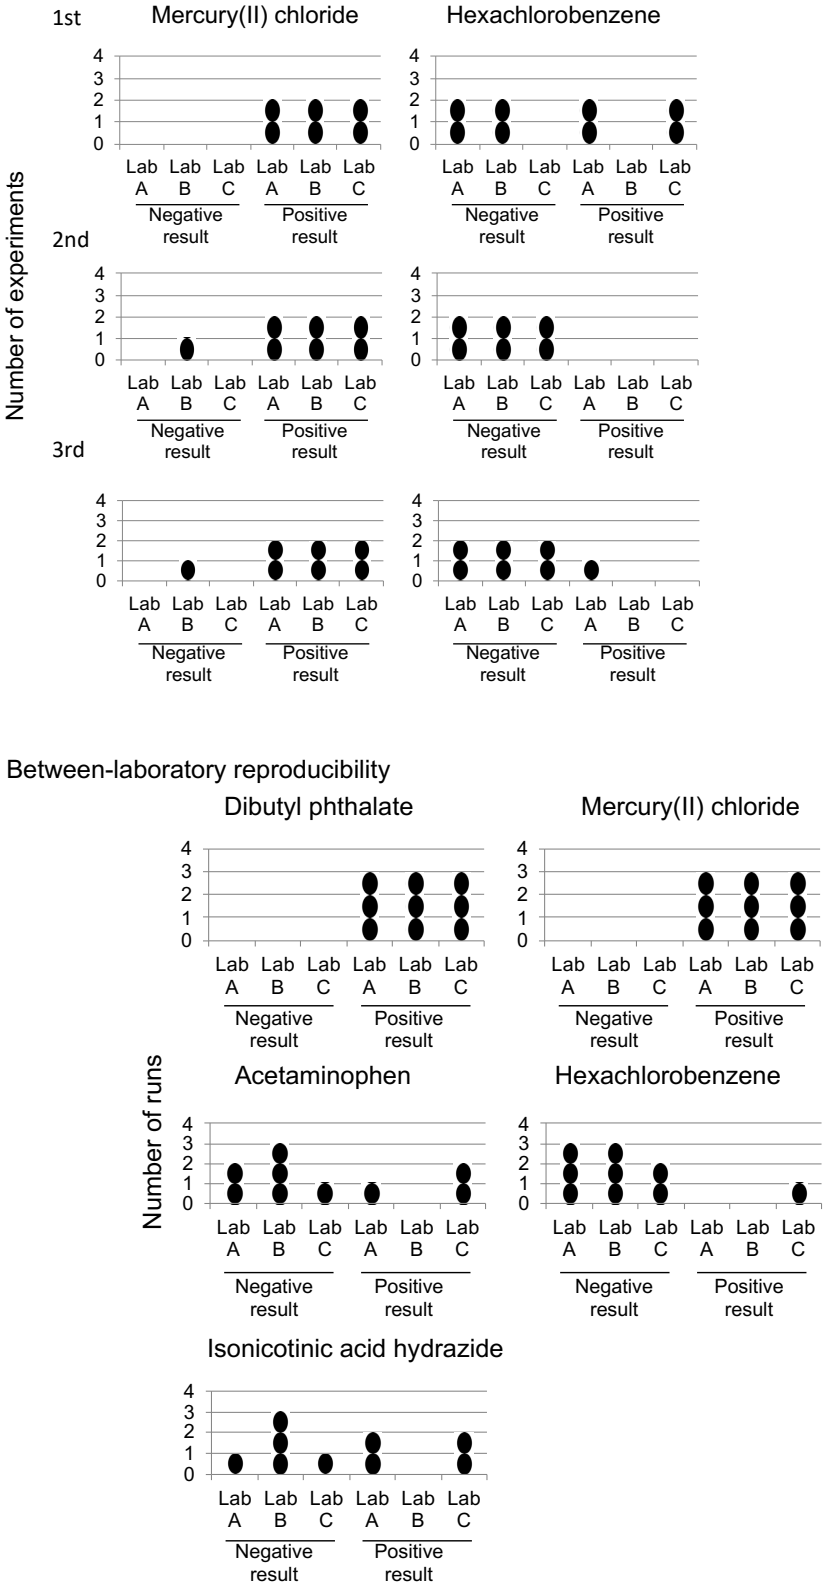


Fig. 9. Between- and within-laboratory variation assessments in Phase I study

The Phase I study examined within-and between-laboratory reproducibilities using a total of five coded chemicals (five immunotoxic chemicals and no non-immunotoxic chemicals) evaluated by three experimental sets based on the MITA protocol for THP-G1b ver. 008E. Closed circles represent the judgments for individual experiments for within-laboratory reproducibility or the judgments in individual experimental sets for between-laboratory reproducibility.

After the Phase I study, we amended the protocol as follows:

- We changed the fold induction for nIL1LA of LPS wells without chemicals to >5 in the acceptance criterion to the fold induction for nIL1LA of LPS wells without chemicals >3.
- For assaying highly cytotoxic chemicals, a new acceptance criterion was added: “If the number of concentrations that satisfy Inh-GAPLA >0.05 is less than 6, the experiment is accepted only when viable wells satisfy the following positive criteria and then, the following experiments should be conducted using in Section 5-1 of Multi-Immuno Tox Assay protocol for THP-G1b ver. 009E (Appendix 6).
- In this assay, since LPS is very potent, a minute variation in the amount of added LPS results in a large variation in nSLG-LA. Therefore, when chemicals have no effect or some stimulatory effect on nSLG-LA, a small variation in LPS concentration causes a significant variation in nSLG-LA. Indeed, there is much more variation in the data showing augmentation than in the data showing suppression. We therefore proposed that the judgment of IL-1 LA is suppression or non-suppression, with the latter including both no effect and augmentation. Indeed, even though we classify chemicals into the categories, suppression, augmentation or no effect, judging a chemical effect as augmentation will cause significant problems when we evaluate the predictivity of this chemical because it is difficult to find chemicals in the literature that further stimulate IL-1 production by monocytes stimulated with LPS.
- The lead laboratory found that some chemicals that should be judged as no effect gave results with Suppression (%) greater than 20. In particular, at 2000 μg/mL,

significant numbers of chemicals showed more than 20% suppression, likely due to high osmotic pressure caused by such a high concentration of dissolved chemical. It was proposed that the threshold should be 25% suppression and that the results at 2000 μg/mL should be excluded.

The following are the final acceptance criteria and criteria for judgment accepted by the internal expert members (Multi-ImmunoTox Assay protocol for THP-G1b ver. 009E).

Acceptance criteria

- If the fold induction of nIL1LA of LPS wells without chemicals (= (nIL1LA of THP-G1b cells treated with LPS)/(nIL1LA of non-treated THP-G1b cells)) is less than 3, the results obtained from the plate containing the control wells should be rejected.
- If the number of concentrations which satisfy Inh-GAPLA >=0.05 is less than 6, the experiment is accepted only when viable wells satisfy the following positive criteria and then, the following experiments should be conducted using the concentration described in Section 5-1 of Multi-Immuno Tox Assay protocol for THP-G1b ver. 009E (Appendix 6).

Criteria

The experiments are repeated until two consistent positive results or two consistent "non-suppression" results are obtained. When two consistent results are obtained, the chemicals are judged as the obtained consistent results.

An immunotoxicant is identified by the mean of Suppression (%) and its 95% simultaneous confidence interval.

In each experiment, when a chemical clears the following four criteria, it is judged as suppression. Otherwise, it is judged as non-suppression.

1. Suppression (%) is $\geq$ 25 with statistical significance. Statistical significance is judged when the 95% confidence interval does not include 0.
2. The result shows two or more consecutive statistically significant positive data points or one statistically significant positive data point with a trend in which at least three consecutive data points increase in a dose-dependent manner. In the latter case, the

trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained at the concentration at which Inh-GAPLA is $\geq$ 0.05
4. The results at 2000 μg/mL are excluded.

9-3-6. Within-laboratory variation assessments in Phase I study when new criteria are applied.

Lab A	100.0% (5/5)
Lab B	100.0% (5/5)
Lab C	100.0% (5/5)
Average	100.0% (15/15)

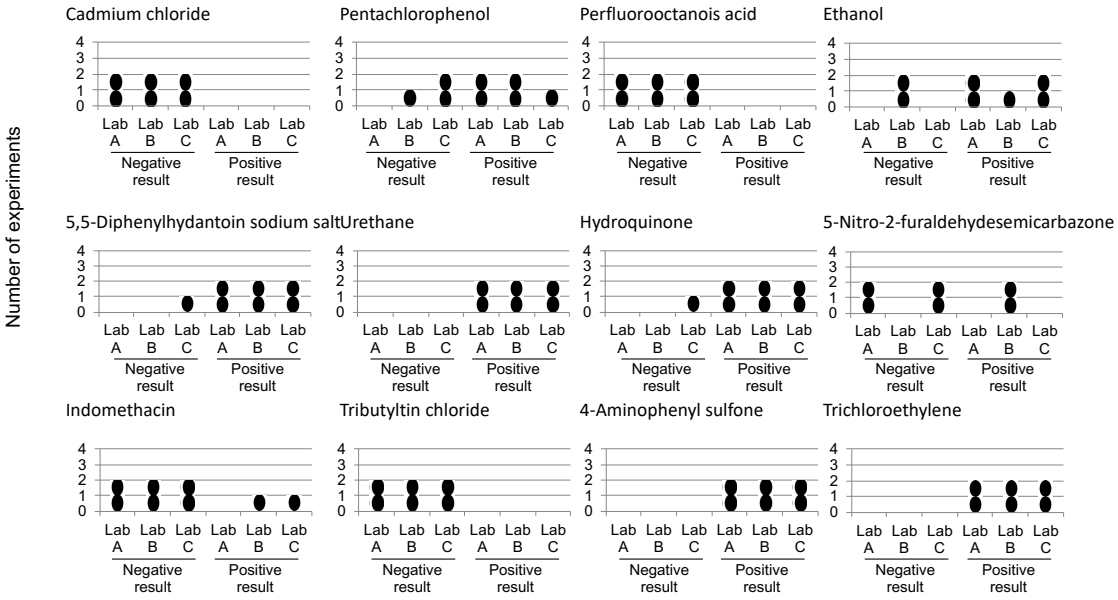
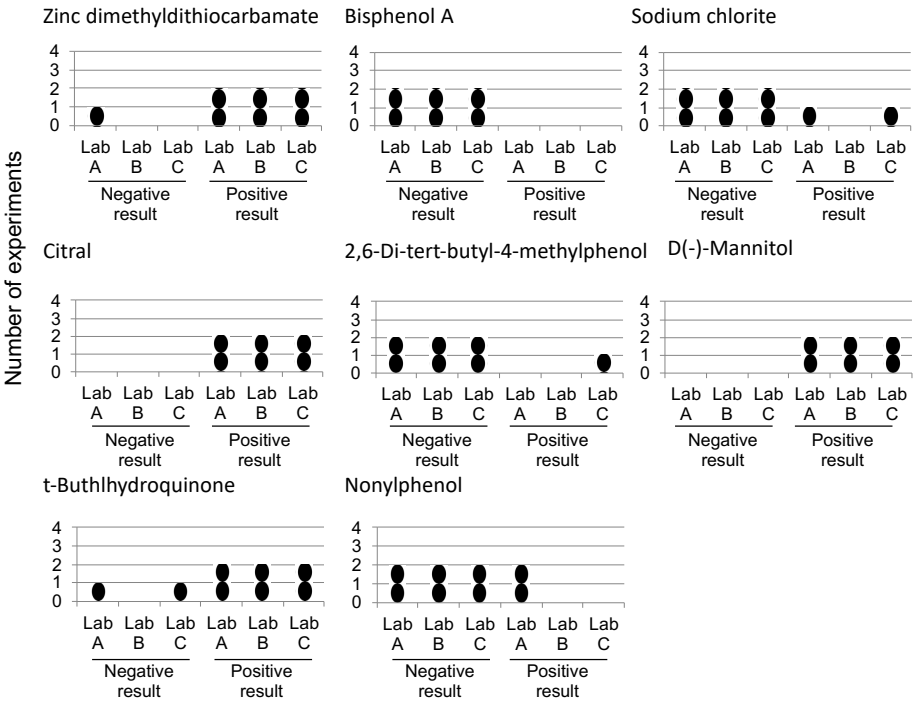
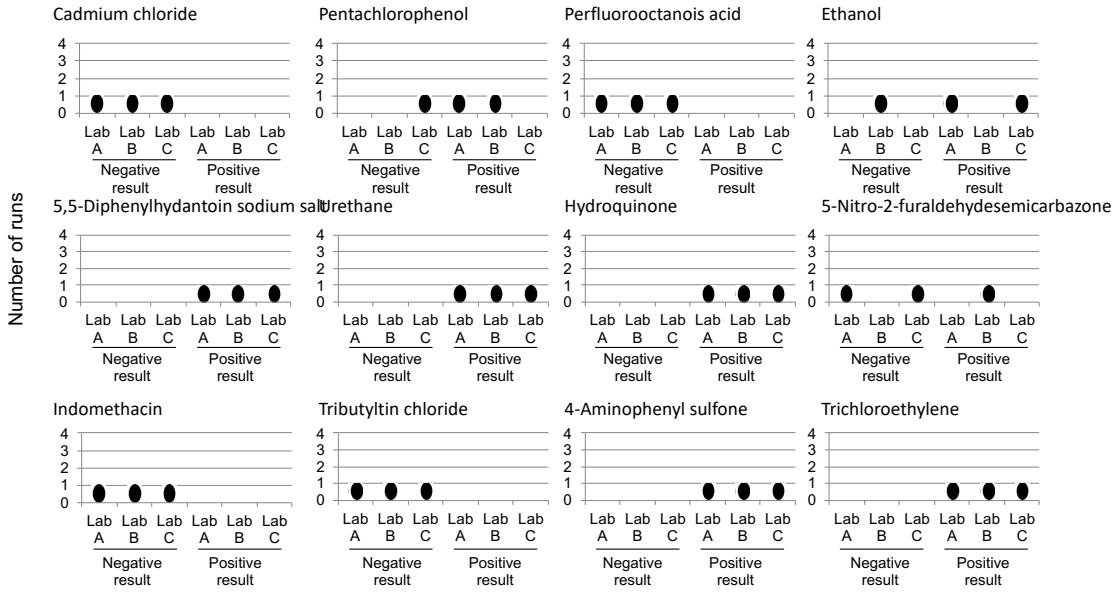
A graphical presentation of between- and within-laboratory variation in the Phase II study is shown in Fig. 11.





Between-laboratory reproducibility



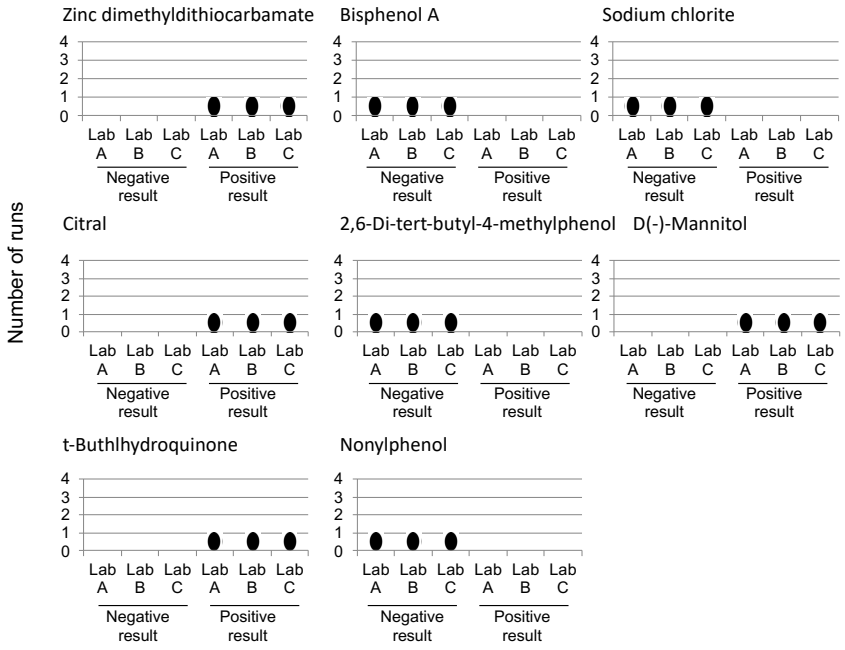


Fig. 11. Between-laboratory variation assessments in Phase II study

The Phase II study examined between-laboratory reproducibility using a total of 20 coded chemicals (15 immunotoxic chemicals and five non-immunotoxic chemicals) evaluated by one experiment set based on Multi-ImmunoTox Assay protocol for THP-G1b ver. 009E. Closed circles represent the judgments for individual experiments for within-laboratory reproducibility or represent the judgments in individual experimental sets for between-laboratory reproducibility.

9-5. Quality assurance

No accidents occurred during the course of the validation study, and all test facilities returned the MSDSs for the test chemicals to JaCVAM in sealed envelopes upon completion of the validation study. All test chemicals were disposed of in compliance with the rules and regulations of the test facilities upon completion of the validation study.

All the records (data sheets and record sheets) from the participating laboratories were checked by Dr. Takashi Omori, Kobe University, and JaCVAM (See Appendix 17-1 and 17-2). The record sheets include “Reagent records, Solubility test, Cell culture records, Test records and Data sheets”. They are more than 300 pages long in total and

are available at the JaCVAM website (http://www.jacvam.jp/validation08-login.html). Tests performed as part of a validation study were carried out in accordance with the principles of GLP (OECD 1998) and necessarily included, but were not limited to, the use of protocol and adequate recording of data as well as suitable reporting of results and archival record keeping.

Cell culture, preparation and application of the test chemicals, and generation of the data sheets were completed and the results accurately reflected the raw data. Unfortunately, the record sheets for maintenance of the measuring instruments were not collected prior to the validation study. JaCVAM thus had concerns regarding the quality of the data in the validation study. However, JaCVAM checked carefully all the results and judged all data to be within the acceptable range.

The reliability of the measuring instruments was checked by an independent organization before the validation study. JaCVAM recommended to the validation management team that the formal validation study be conducted with GLP laboratories.

9-6. Combined results of Phase I and II studies (for between- and within-laboratory reproducibility and predictive capacity)

9-6-1. Test conditions

The within- and between-laboratory reproducibilities, and the predictivity of the IL-1 Luc assay, were evaluated using all the results from Phases I and II.

9-6-2. Within- and between-laboratory variation assessments from Phase I and II studies.

Between-Lab reproducibility 84.0% (21/25)

Within-Lab reproducibility

Lab. A 100.0% (5/5)

10. Discussion

10-1. Reliability

The IL-1 Luc assay is based on the modulation of LPS-induced luciferase activity in the IL-1β reporter cell line, THP-G1b. Therefore, it is important that THP-G1b cells retain their ability to induce luciferase activity after LPS stimulation even after passage for a sufficient number of times to perform the assay in the long term. We confirmed that a frozen stock of THP-G1b cells can be cultured without losing luciferase activity for at least 16 weeks or 33 passages.

Culturing of THP-G1b cells is relatively simple and does not require the use of trypsin or EDTA because THP-G1b cells do not adhere to the culture dishes. First, chemicals at graded concentrations are added to the wells of a 96-well culture plate. Then, cells adjusted to the optimum concentration are seeded into each well. After 6 h incubation, 100 μL of pre-warmed Tripluc Luciferase Assay Reagent is added to each of the 96 wells. The subsequent process is completely automated, except for calculating the results using the predesigned Excel spreadsheet. Therefore, the IL-1 Luc assay is a test method that can significantly reduce human error.

Moreover, the IL-1 Luc assay does not require the determination of cell viability after chemical treatment. THP-G1b cells can present IL-1β promoter activity as well as promoter activity of GAPDH, a well-known housekeeping gene; therefore, information regarding the effects of the chemical on both IL-1β promoter activity and cell viability is obtained in each experiment. Furthermore, a single experiment takes only 8 h, including the time required for chemical preparation and cell plating, indicating that the IL-1 Luc assay is a true high-throughput method.

10-2. Between- and within-laboratory reproducibility

We examined within-laboratory reproducibility in the Phase I study. Lab A, Lab B, and Lab C demonstrated 100%, 100%, and 100% reproducibility, respectively. On the other hand, the between-laboratory reproducibility result for Lab A, Lab B, and Lab C

was 84.0% for the combined data of the Phase I and Phase II studies. These results satisfied the acceptance criteria for the validation study of a within-laboratory reproducibility of at least 80% and a between-laboratory reproducibility of at least 80%.

10-3. Predictivity

10-3-1. Predictivity of Phase I and Phase II studies

As described in the Background section, the immunotoxicity test can target global immunotoxicity or a specific immune response. Since IL-1β has pleiotropic functions in immune response, it could potentially be used as a global immunotoxicity test. Therefore, we first examined the predictivity of the IL-1 Luc assay in detecting immunosuppressants. According to the procedure used to determine the predictivity of the IL-2 Luc assay (Kimura et al. 2020), we first constructed reference data for making positive or negative judgments by collecting literature information on the eight endpoints for each chemical and identifying chemicals that satisfied one of the three criteria for immunotoxic chemicals. Based on these reference data, the IL-1 Luc assay performance was 41.7% for mean sensitivity, 60.0% for mean specificity, and 45.3% for mean prediction for the combined data from the Phase 1 and Phase 2 studies. These data suggest that the IL-1 Luc assay alone cannot detect chemicals with global immunotoxicity and must be used in combination with other global immunotoxicity tests.

10-3-2. IL-1 Luc assay data set for 63 chemicals

To clarify the characteristics of the IL-1 Luc assay, the lead laboratory evaluated the data for 60 chemicals previously evaluated by the IL-2 Luc assay (Kimura et al. 2020) and three new chemicals added in this study, and evaluated by the IL-1 Luc assay. To determine the performance of the IL-1 Luc assay for these 63 chemicals, we referred to reference data generated by collecting literature information on the eight endpoints for each chemical (Appendixes 12 and 13) and identifying chemicals that satisfied at least one of the three criteria as immunotoxic chemicals. The summarized

immunotoxicity information, together with the classification of each chemical, are shown in Appendixes 14 and 15. The judgment of these chemicals by the IL-1 Luc assay is shown in Table 20, and the judgment by the IL-2 Luc assay is also shown for comparison. The performance of the IL-1 Luc assay was 53.1% for sensitivity, 35.7% for specificity, and 49.2% for predictivity (Table 21). Again, these data suggest that the IL-1 Luc assay alone is not sufficient to detect chemicals with global immunotoxicity. On the other hand, the performance of the IL-2 Luc assay was 69.4% for sensitivity, 21.4% for specificity, and 58.7% for predictivity, when the same reference data used for the IL-1 Luc assay was applied. Although the performance of the IL-2 Luc assay is better than that of the IL-1 Luc assay, it is also insufficient to be used as an immunotoxicity test alone. Next, we examined the performance of the combination of the IL-1 Luc assay and the IL-2 Luc assay. It improved the performance of the IL-2 Luc assay from 69.4% to 73.5% for sensitivity and from 58.7% to 61.9% for predictability (Table 22 and 23). Even after combining these two assays, its performance is insufficient to cover the immunotoxicity of whole chemicals. Probably, the performance of the assay will be improved by the IATA combining various immunotoxicity tests that target different aspects of our immune responses step by step. The combination of the IL-1 Luc assay and the IL-2 Luc assay can be the first step of this IATA approach.

Next, we compared the judgment for 63 chemicals by the IL-1 Luc assay with that by the IL-2 Luc assay and found that 31 of 33 chemicals that were judged as exhibiting suppression by the IL-1 Luc assay were also judged as exhibiting either suppression or augmentation by the IL-2 Luc assay. In contrast, 31 of 47 chemicals that were judged as exhibiting either suppression or augmentation were judged as exhibiting suppression by the IL-1 Luc assay.

This significant overlap of suppression judgment is likely due to the signaling pathway of TLR4 stimulation to induce IL-1β mRNA being at least partially shared by the signaling pathway for PMA/Io stimulation to induce IL-2 mRNA.

As described in section 3-2-2, LPS stimulation leads to the activation of several transcription factors, including NF-κB, CREB/ATF, c/EBPb, AP1 and IRF3 (reviewed

by Newton et al. (Newton and Dixit 2012)). Although the relative contributions of these factors to IL-1β transcription are currently unclear, the IL-1 Luc assay is considered a test method for finding chemicals that primarily block the NF-κB, AP1 and p38a MAPK signaling cascades after TLR4 receptor stimulation.

On the other hand, the simultaneous stimulation of PMA and calcium ionophore or ionomycin is known to mimic the stimulation by T cell receptor (TCR) and CD28 (Kumagai et al. 1987; Truneh et al. 1985; (Gholijani et al. 2015). In addition, the signaling pathways leading to IL-2 transcription after PMA/Io stimulation overlap significantly with the signaling pathways leading to IL-2 transcription after T cell receptor and CD28 stimulation. In fact, both stimulations ultimately activate NF-AT, c-Fos, c-Jun and NF-κB (Gholijani et al. 2015; Lee et al. 1994).

These data suggest that TLR4 stimulation and PMA/CI stimulation share at least a part of the signaling pathway leading to the activation of NF-κB. Indeed, TLR4, TCR/CD28 and PMA stimulation is known to activate the canonical pathway of NF-κB (Meininger and Krappmann 2016; Vallabhapurapu and Karin 2009; Wang et al. 2011). Therefore, it is quite reasonable that the two assays share the same judgments for a significant number of chemicals (Fig. 12).

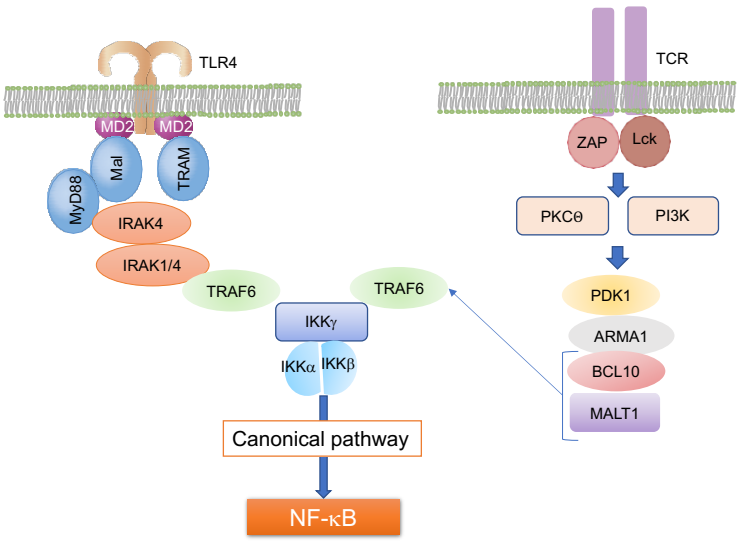

Fig. 12. The signaling cascade of TLR4 stimulation and TCR stimulation leading to NF-κB

10-4. IL-1 Luc assay as novel assay for evaluating effects of chemicals on TLR4 receptor and IRAK4.

Although TLR4 and PMA/Io stimulate the canonical pathway of NF-κB, their upstream signaling to activate the canonical pathway differ. TRAF6 used to activate the canonical pathway by TLR4 stimulation is likely involved in the activation of the canonical pathway by T cell receptor activation (Sun et al. 2004; Vallabhapurapu and Karin 2009), and thus upstream signaling to stimulate TRF6 can be different between TLR4 stimulation and PMA/Io stimulation (Fig. 12).

Indeed, the signaling cascade leading to TRAF6 activation after TLR4 stimulation comprises at least TLR4, Mal, TRAM, Myd88, IRAK4 and IRAK1/2, which are not shared by TCR signaling. IRAK4 is a key signaling node for transducing the responses of the interleukin-1 (IL-1) receptor family (IL-1, IL-18, and IL-33 receptors), and TLRs (except for TLR3) have recently attracted widespread attention as therapeutic targets for inflammation and tumor diseases (Chaudhary et al. 2015). We therefore examined the effects of TAK-242 and VIPER, inhibitors of TLR4 (Matsunaga et al. 2011) (Lysakova-Devine et al. 2010) and of PF06650833, an inhibitor of IRAK4 (Lee et al. 2017) using the IL-1 Luc assay and the IL-2 Luc assay. As expected, both inhibitors significantly suppressed IL1LA, suggesting the utility of the IL-1 Luc assay in identifying chemicals that block TLR4 signaling upstream of TRAF6 activation. Although PF06650833 significantly suppressed IL2LA in the IL-2 Luc assay, the LOWEL to suppress IL2LA in the IL-2 Luc assay was 400 times higher than that to suppress IL1LA in the IL-1 Luc assay. Consistently with the finding, the role of IRAK4 in T-cell receptor signaling to activate NF-κB has been reported (Suzuki and Saito 2006).

Currently there is no high-throughput approach to detect the effects of chemicals or drugs that target TLR4, Mal, TRAM, Myd88, IRAK4 or IRAK1/2. In addition, some of these molecules are also used in the signaling cascade after the stimulation of other TLRs and IL-1R (Suzuki and Saito 2006). The IL-1 Luc assay is a promising tool for detecting the immunotoxicity of chemicals that target these molecules.

10-5. Factors responsible for false negative results in IL-1 Luc assay

Although the within- and between-laboratory reproducibility results satisfied the acceptance criteria for the validation study, the predictivity was far less than 80%, likely because the IL-1 Luc assay does not cover every aspect of the effects of the chemicals on the global immune response. In addition, like other *in vitro* tests, the IL-1 Luc assay does not have metabolic activity and cannot evaluate water insoluble chemicals.

10-6. Applicability domain and limitations of IL-1 Luc assay

The IL-1 Luc assay is not intended to evaluate global immunotoxicity alone. This assay can evaluate the effects of chemicals that affect the signaling pathway to activate NF-κB, AP1 and p38a MAPK in innate immune cells, especially after TLR4 receptor stimulation. Chemicals that potentially induce immunosuppression by other signaling pathways are not suitable for the IL-1 Luc assay. In addition, chemicals that require metabolic activation or are water insoluble fall outside the applicability domain.

10-7. Regulatory application of the IL-1 Luc assay

The CAS REGISTRY^{SM} currently contains more than 130 million unique organic and inorganic chemical substances, such as alloys, coordination compounds, minerals, mixtures, polymers, and salts. Humans are exposed to many of these substances, which are present as environmental contaminants or used as food additives and drugs. Some of these compounds can target the immune system, resulting in adverse health effects such as the development of allergies, autoimmune disorders, increased susceptibility to infection and cancer, and other diseases. Accordingly, immunotoxicity, which is defined as the toxicological effects of xenobiotics on the function of the immune system, is a matter of serious concern to the public as well as regulatory agencies. To address these concerns, the World Health Organization published its Guidance for Immunotoxicity Risk Assessment for Chemicals (World Health Organization (WHO). Currently, the assessment of chemical immunotoxicity relies mainly on animal models and assays that

characterize immunosuppression and sensitization. However, animal studies have so many drawbacks, such as high cost, ethical concerns, and questionable relevance to risk assessment for humans, that they cannot be used to screen the immunotoxicity of more than 130 million chemicals. Therefore, there is an urgent need to develop alternative testing methods and assessment strategies to reduce the use of laboratory animals and, if possible, replace animals used in scientific studies (Adler et al. 2011). To date, however, there are no OECD test guidelines to detect chemical immunotoxicity *in vitro*. We would therefore like to propose the IL-1 Luc assay, and the MITA in the near future, as a screening toolbox of alternative test methods for immunotoxicity. Finally, the VMT recommend that the proficiency chemicals (Appendix 18) to users and the performance standard chemicals (Appendix 19) to me-too validation study.

11. Conclusion

Using three luciferase reporter cell lines, we established the MITA, in which the effects of chemicals on IL-2 and IFN-γ promoter activity of 2H4 cells and those on IL-1β and IL-8 promoter activity of THP-G1b and THP-G8 cells can be evaluated. Here, we conducted a validation study of the IL-1 Luc assay among the four luciferase assays that comprise the MITA. The results of both Phase I and Phase II studies satisfied the acceptance criteria for the validation study. Although a predictivity of 80% was not attained, it may nonetheless be acceptable when considering the applicability domain , limited targets of the IL-1 Luc assay, and future use as one of the components of the IATA. We would therefore like to propose the IL-1 Luc assay as the OECD test guideline for *in vitro* immunotoxicity tests.

12. Acknowledgement

This validation study was supported by Grants-in-Aid from the Ministry of Economy, Trade and Industry (METI), the Ministry of Health, Labor and Welfare (MHLW), and the Japanese Society for Alternatives to Animal Experiments (JSAAE).

We gratefully acknowledge voluntary work by the participating laboratories and the European Union Reference Laboratory for Alternatives to Animal Testing (EURL-ECVAM), and the NTP Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM).

Appendix 01 IL-1b Study plan Ver1.0

Version 1.0 September, 2018

Study plan for the validation trial on multicolor reporter assay using THP-G1b (TGCHAC-A4) (IL-1β Luc assay) as a test evaluating the immunotoxic potential of chemicals

Conducted by:

IL-1β Luc assay Validation Management Team

INDEX

1./ Background

2./ Objective of the trial

3. Validation Management Team

4. Protocol

5. Chemical

6. Records and archiving

7. Study timeline

1. Background

The use of multicolor reporter assay using THP-G1b (TGCHAC-A4), IL-1β Luc assay is an important for evaluating the immunotoxic potential of chemicals as a part of Multi-ImmunoTox assay (MITA), because of its technical simplicity, short-term test period and accuracy of test result based on a mechanism of immunotoxicity.

The aim of this trial is to (pre)validate the IL-1β Luc assay method to assess transferability and inter-laboratory variability, in order to incorporate this test for screening the immunotoxic chemicals. The IL-1β Luc assay for the validation trial will be undertaken i) in accordance with the principles and criteria documented in the OECD No. 34 Guidance Document on the Validation and International Acceptance of New or Updated Test Methods for Hazard Assessment [OECD, 2005], ii) according to the Modular Approach to validation [Hartung et al., 2004] ,iii) according to the concept discussed on the validation trials with participation of GLP Test Facilities [Cooper-Hannan et al., 1999] where the whole concept of the validation trials is described in the context of GLP, iv) and in line with the ISO procedure JRC.I.03.GP.01v.01 (http://ihcpnet.jrc.it/quality-safety/quality-documents/unit-03-ivm/doc/JRC.I.03.GP.01v.01.pdf).

The studies part of a validation trial should ideally be performed in accordance with GLP [OECD, 1998-2007; FDA, 1999; EPA, 1998a&b; JSQA, 2010; SCC, 2010]. As a minimum, but not necessary limited, use of standard operating procedures (SOP), adequate data recording, reporting and record keeping are essential.

A general conceptional framework [Hartung et al., 2004; OECD, 2005] will be used

for documenting all the study to assess the validation status of a test method, called "modular approach" to validation. In this approach, the information needed to support the validity of the method is organized into modules that provide the following information:

Module 1: Test Definition

Module 2: Within-laboratory repeatability and reproducibility

Module 3: Between-laboratory transferability

Module 4: Between-laboratory reproducibility

Module 5: Predictive capacity

Module 6: Applicability domain

Module 7: Performance standards

The Modular approach as introduced by Hartung et al., allows using datasets from various data sources and studies. This advantage is used in the following proposal to assess the scientific validity of the IL-1β Luc assay. The IL-1β Luc assay for the validation trial has performed under the GLP principle.

2. Objective of the trial

The validation trial will assess the reliability (reproducibility within and between laboratories) and relevance (predictive capacity) of the IL-1β Luc assay with a challenging set of test substances (test items) for which high quality *in vitro and in vivo* data are available.

3. Validation Management Team (VMT)

The VMT encompasses collective expertise with the test, in the underlying science

and the scientific design, management and evaluation of a validation trial.

The VMT, which plays a central role overseeing the conduct of the validation trial, includes:

Table 1. Members for IL-1β Luc assay Validation Management Team

Name	Role and expertise	Affiliation
Trial Coordinator Hajime Kojima	VMT trial coordinator , Management of quality control	JaCVAM, NIHS, Japan (JaCVAM representative)
Lead Lab Yutaka Kimura* Setsuya Aiba*	*Developer of this assay Test method, expertise underlying science	Tohoku Univ., Japan
Takao Ashikaga	Chemical supplier	JaCVAM, NIHS, Japan (JaCVAM representative)
Takashi Omori	Data analysis, biostatistics dossier	Kobe Univ., Japan
International expert members		
EU liaison Emanuela Corcini	Test system expertise, validation expertise, immunotoxicity expertise	Milan Univ., Italy
EU liaison Erwin L. Roggen,	Test system expertise, validation expertise, immunotoxicity expertise	3Rs Management and Consulting ApS, Denmark
ICCVAM liaison Dori Germolec	Immunotoxicity expertise	NTP/NIEHS, USA
JSIT liason Tomoaki Inoue	Immunotoxicity expertise	Chugai Pharmaceutical Co., Ltd.

3.1 Participating Test Facilities

The laboratories participating in the trial are defined as follow:

Test Facility 1: Hatano Res. Inst., FDSC. Study Director (SD) : Kohji Yamakage

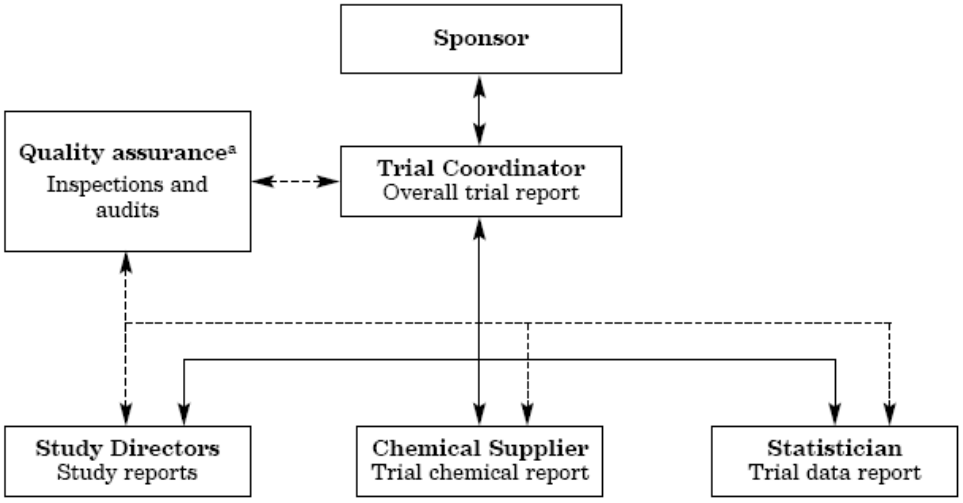
Test Facility 2: AIST, Tsukuba SD : Rie Yasuno

Test Facility 3: AIST, Takamatsu SD : Yoshihiro Nakajima

Information relevant for Modules 1, 2, 3 performed by all laboratories. Data obtained by these laboratories have demonstrated that the IL-1B Luc assay is transferable and reproducible between experienced laboratories. The all facility will be the laboratory participating in this validation trial acting as unexperienced laboratory to assess between laboratory transferability, reliability and relevance of the IL-1B Luc assay method under non-GLP conditions (GLP principle).

3.1 Trial management structure

The management structure of the validation trial is shown in **Figure 1**



[a]Several Quality Assurance units might be involved in a multi-study trial.
Dashed lines indicate assurance staff involvement.

Figure 1: Management Structure of the IL-1β **Luc assay validation trial**

1) Chemical management group

The members of chemical management group are elected by recommendation of the IL-1β Luc assay VMT. They prepare a tentative list of test chemicals and works with the VMT to make a final decision on the test chemicals to be used in the validation trial. The coded test chemicals listed are distributed by JaCVAM.

2) Data analysis group

The members of data analysis group are elected by recommendation of the IL-1β Luc assay VMT, and check and analyze the data obtained in this validation trial from a third-party standpoint. They also take charge of statistical processing in this validation trial.

3) Quality assurance group

The members of record management group are elected by recommendation of the

IL-1β Luc assay VMT. They prepare protocol, test chemical preparation record forms, blank data sheets, etc. and distributes them to the research laboratories participating in this validation trial. They also collect filled out forms and data sheets after completion of experiments, pointing out omissions or flaws in recording, if any, and requesting correction of such errors.

4) Lead laboratory

The lead laboratory representing the test method is responsible for providing the test method protocol and the eventually necessary data recording or calculation templates. The Trial Coordinator has to ensure that such data recording or calculation templates have been validated before distribution to the test facilities involved in the validation trial. The lead laboratory is also responsible for providing, if necessary, new versions of the protocols during the entire validation trial. The lead lab and the other participating test facilities might be contacted by the VMT for technical issues.

3.2 Sponsor

The validation trial for assessing the validity of IL-1β Luc assay will be financed by the Ministry of Health, Labour and Welfare (MHLW), Japan.

The lead laboratory will support the IL-1β Luc assay validation trial by assuring that reliability is assessed. At the same time, preliminary results of the test method can be evaluated. For this purpose, Lead laboratory will support:

- the financial aspects related to the coordination of a validation trial (e.g. organization of VMT meetings where also the involved test facilities can be invited for technical clarifications to the VMT, the publication of the validation

trial results)

- the test, reference and control item purchase, coding and distribution to the test facility
- the availability of the test systems to the participating laboratories by supporting the Lead laboratory with the logistics for delivering the test system to the facility
- the independent data analysis and statistical support (biostatistician) based on the study reports generated
- the other costs for participating laboratories

3.3 Trial coordination

Dr. Hajime Kojima was appointed as the Trial Coordinator with well-defined roles and responsibilities to coordinate the trial and to establishment of a VMT by supporting of JaCVAM.

The name and location of the Trial Coordinator should be identified in each individual study plan. For the IL-1β Luc assay validation trial, the Trial Coordinator has direct access to the test item coding.

The Trial Coordinator's responsibilities include:

a) Establishment of/support to lead laboratory, including meeting organization

b) Trial communication and coordination with test facilities

c) Recording of document and data flow between test facilities

d) Assessing and documenting the impact of any amendments and/or deviations from the trial plan and study plans on the quality and integrity of the validation trial

e) Ensuring that the individual study reports are forwarded, in a timely manner, for data and statistical analysis

f) Preparing the trial plan and report, which can be based on the study reports from the lead laboratories and other test facilities involved in the validation trial, and should reflect the overall trial

g) Approval with date and signature of all protocols, Study Plans and Study Reports

h) The communication of the results of the trial into the public domain

The role of Trial Coordinator (as the formal representative of the VMT and the single contact point with the SDs) is of fundamental importance. The Trial Coordinator is the single critical point of trial control and must ensure clear lines of communication between the involved test facilities in the trial. The communication line of the Trial Coordinator is with the SDs of the different test facilities. The SDs are the single point of contact with the Trial coordinator (unless otherwise communicated by the participating Test Facilities) to assure a transparent and recorded documentation flow during the trial. The Trial Coordinator should also ensure that appropriate arrangements have been made for the supply of the test systems, and test, control and reference items, which meet the requirements of the trial, and that there are appropriate test method protocols (dated signature by the trial coordinator and the Lead Laboratories) and, if appropriate, validated data recording, data analysis, data reporting sheets for the test method.

It is the responsibility of the Trial Coordinator to approve the study plans send for approval by the test facilities, and any amendments to the study plan, by dated signature.

3.4 Training

The lead laboratory will be responsible for issuing a training agenda to the Trial Coordinator for further distribution to the all test facility giving details what training aspects will be covered during the training of the other SDs and Study Personnel at the lead laboratory. Furthermore, after the training, the lead laboratory will issue to the Trial Coordinator a training report and indicating if critical observations are made by the other test facilities regarding the IL-1β Luc assay protocols. In case any critical observations are made a new version of the IL-1β Luc assay protocols might necessary be issued to the other test facilities before initiating the between-laboratory transferability.

3.5 [Module 3] Between-laboratory transferability

This between-laboratory transferability (Module 3, identical to ICCVAM proficiency testing phase) is performed in order to assess the successful transfer of the assay to a test facility unexperienced with that particular test method but having knowledge of similar test systems and endpoint detection methods.

For the transfer of IL-1β Luc assay to the all test facility, the Phase 0 study using non-coded three chemicals was performed. A few concentrations of each test item will be tested in triplicate in 2 independent runs according to the IL-1β Luc assay protocol describing the details of the experimental design. The results of the between-laboratory transferability will be reviewed before progressing with module 4 on the between laboratory reproducibility. If the transferability data do not meet test acceptance criteria, the Trial Coordinator representing the VMT will try to identify the problems

and make corrections where needed.

3.6 [Module 2] Within-laboratory reproducibility

The within-laboratory reproducibility of the all test facility has been done by an independent biostatistical analysis, under the VMT. The proportion of concordance should be equal or more than 80% as tentative acceptance criteria for phase I validation.

The five test items selected for the phase I study are coded as follows: A, B, C, D, and E. The all facility will prepare a study according to internal GLP principle. This plan will be submitted to the Trial Coordinator and lead laboratory for approval.

At the end of the testing, the test facilities will submit a QC certified copy of whole study dossier to the Trial Coordinator (study plan in GLP principle, raw data, records and data analysis, study report in GLP principle).

3.7 [Module 4] Between-laboratory reproducibility

Ten coded test items have been selected to confirm the between-laboratory reproducibility in the phase I study. A few concentrations of each test item will be tested in triplicate according to the IL-1β Luc assay method protocol describing the details of the experimental design.

At the end of the testing, the test facilities will submit a QC certified copy of whole study dossier to the trial coordinator (study plan in GLP principle, raw data, records and data analysis, study report in GLP principle). The proportion of concordance between-laboratory reproducibility should be equal or more than 80% as acceptance criteria,

3.8 [Module 5] Predictive capacity

The necessity for further chemical analysis will be subject to a VMT decision once the data of the between laboratory reproducibility has been assessed. Depending on the statistical analysis the lean design for validation as well as the automatisation of the test leading to an increased dataset will be considered.

4. Protocol

In this validation trial, the protocol (ver. 1E) will be used (attached Document #2). This protocol will make up a draft by the lead laboratory and be finalized by VMT.

A measurement of bioluminescence intensity induced with chemical treatment will be measured by luminometer (Phelios: ATTO, Cat #:AB-2350) calibrated using stabilized SLG, SLO and SLR enzymes in this validation trial.

5. Chemicals

5.1 Chemicals Selection

Test chemicals have been selected by chemical repository based on published papers on in vivo immunotoxicity

The applied selection criteria were:

- information on mode/site of action
- coverage of range of relevant chemical classes and product classes quality and quantity of reference data (*in vivo* and *in vitro*)
- high quality data derived from animals and (if available) also humans
- knowledge on interspecies variations (for example: variability with regard to the uptake of chemicals, metabolism, etc.)
- coverage of range of toxic effects/potencies
- chemicals that do not need metabolic activation

- appropriate negative and positive controls
- physical and chemical properties (feasibility of use in the experimental set-up as defined by the CAS No.)
- single chemical entities or formulations of known high purity
- availability
- costs

In the first phase of the selection procedure, the Chemical Selection Committee identified and collected several existing lists of potential chemical sensitizing in order to establish a primary database. These chemicals had originally been compiled by international experts for various purposes e.g. as reference compounds for validation studies. An extensive literature research was performed by the Chemical Selection Committee in order to insure that the preselected chemical fulfilled the selection criteria described above.

Emphasis was laid on the fact that different potencies (strong, weak and no activity) have been chosen. In addition, it was decided that at least 20% of the total substances to be tested should be negative in order to increase the statistical power of the data analysis.

In the first phase IL-1β Luc assay validation trial with data generation at the test facilities, five chemicals will be tested three times in each test chemical for between-laboratory reproducibility and to confirm transferability. After discussion of Phase I results, detailed test planning of the Phase II will be determined. At this moment, twenty chemicals will be planned in the phase II trial for predictive capacity (Table 2).

Table 2. Outline of test planning at each study in the validation trial.

Study	Chemicals	Test Number	Information obtained
Phase 0	3 non- coded	2	Between-lab transferability
Phase I	5 coded	3	Within & between-lab reproducibility
Phase II (planning)	20 coded	1	Between-lab reproducibility & predictability

(Planning of Phase II will be determined after discussion of the results of Phase I)

5.2 Chemicals Acquisition, Coding and Distribution

The assessment of within-laboratory reproducibility (Module 2), between laboratory transferability (Module 3) in the all test facilities have been performed with coded chemicals. This IL-1β Luc validation trial plan describes the generation of the missing data sets under coded test item. If the results obtained are not very similar to the previous obtained sets, the VMT has to assess if coded chemicals need to be tested in the all test facilities.

The coding will be supervised by the Trial Coordinator, in collaboration with the chemical repository responsible of coding and distribution of test, reference and control items for the validation trial.

5.3 Handling

Each test facility shall receive through the Trial Coordinator essential information about the test chemicals (physical state, weight or volume of sample, specific density for liquid test chemicals, and storage instructions). Moreover, the SD should receive

the safety information concerning the hazards identification and exposure controls/personal protection.

6. Records and archiving

At the end of the trial, the IL-1β Luc assay validation trial report is prepared by the Trial Coordinator or the VMT personnel who appointed by the Trial Coordinator. The trial report summarizes the trial goals, procedures, results and conclusions of the validation trial. This represents the whole validation trial, including archiving and, as such, will cover several study reports, as well as reports for test item supply, data management and statistics. The Trial Coordinator oversees the preparation of the trial report. The Trial Coordinator will be representing the VMT discussions responsible for preparation of the scientific conclusions. Signatories to the trial report include the Trial Coordinator, the statistician, and the SDs of the involved test facilities. Although the SDs may not be involved with the preparation of the trial report, their signatures confirm that the trial report is an accurate reflection of the management and study events. The trial report should contain a statement, signed by the Trial Coordinator, commenting on the accuracy and completeness of the trial report and identifying any significant issues which could have affected the integrity of the trial, including matters of GLP compliance. A QC statement will be included in the trial report, in order to identify what QC monitoring was done and to confirm whether or not the trial report is an accurate reflection of the validation trial data.

7. Study timeline

An approximate schedule for IL-1β Luc assay validation trial is shown in Table 3.

Duration of this validation trial is around twenty -month from August 2018 to 2020.

Table 3. Schedule of IL-1β Luc assay validation trial

Month	Activity
August, 2018	Establish the VMT
	Selection of participating research laboratories
	Deliberation, decision and read-through of draft study plan
	Deliberation and decision of protocol
	Preparation of a tentative list of test chemicals
	Distribution of test chemicals, standard chemicals and positive control chemicals
October,2018	Technical transfer using five known chemicals (non-coded) Start of technical transfer **to know between laboratory transferability**
	Data collection of technical transfer (**Phase 0 study**)
Phase I study	
October, 2018	Coding and distribution of five coded test chemicals
November, 2018	Start of Phase I study
March, 2019	End of Phase I study
May, 2019	**2nd VMT Meeting** / Phase I results and planning of Phase II study
Phase II study to know between- and within-laboratory reproducibility	
2019	Coding and distribution of coded test chemicals and positive chemicals
2019	Start of Phase II study using 20 coded test chemicals
2019	End of Phase II study
2020	**3rd VMT Meeting** /reviewing of Phase II study results
2020	Completed validation report

1. Introduction

This protocol describes how to maintain the cells, how to prepare the test chemicals, and how to measure the luciferase activity of THP-G1b (TGCHAC-A4), THP-1 cells transfected with 2 luciferase genes, stable luciferase orange (SLG) on the human artificial chromosome (HAC) vector and stable luciferase red (SLR), under the control of IL-1β and G3PDH promoters, respectively, for the Multi-Immuno Tox Assay.
(Kimura Y. et al. Evaluation of the Multi-Immuno Tox Assay composed of 3 human cytokine reporter cells by examining immunological effects of drugs *Toxicol in Vitro*, 28, 759-768, 2014)

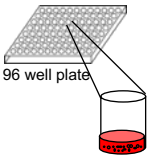
LPS



Cell preparation
(1 x 10^5 cells/well of THP-G1b (TGCHAC-A4))

Add various concentrations of Chemicals

↓Incubate for 1 h

Stimulate with LPS

↓Incubate for 6 h

Add TripLuc® luciferase assay reagent (TOYOBO)

↓Shake for 10 min.

Assess using a microplate-type luminometer (5 min./plate)

2. Materials

2-1 Cells

・ THP-G1b (TGCHAC-A4) (IL1β-SLG、G3PDH-SLR)

The human macrophage-like cell line THP-1 was obtained from the American Type Culture Collection (Manassas, VA, USA). A THP-1-derived IL-1β reporter cell line, THP-G1b (TGCHAC-A4), that harbors the SLG and SLR luciferase genes under the control of the IL-1β and G3PDH promoters, respectively, was established by the Dept. of Dermatology, Tohoku University School of Medicine and GPC laboratory Co. Ltd.
(Kimura Y. et al. Profiling the immunotoxicity of chemicals based on in vitro evaluation by a combination of the Multi-ImmunoTox assay and the IL-8 Luc assay. Archives of Toxicology, 92, 2043-2054, 2018)

2-2 Reagents and equipment

2-2-1 For maintenance of the THP-G1b (TGCHAC-A4) cells

・ RPMI-1640 (GIBCO Cat#11875-093, 500 mL)
・ FBS (Biological Industries Cat#04-001-1E Lot: 715004)
・ 100 X concentrated antibiotic and antimycotic (10,000 U/mL of penicillin G, 10,000 μg/mL of streptomycin and 25 μg/mL of amphotericin B in 0.85 % saline) (e.g., GIBCO Cat#15240-062)

2-2-2 For chemical exposure, stimulation, positive control and solvents

・ Lipopolysaccharide (LPS) from Escherichia coli K12 (Invivogen Cat#tlrl-eklps, Lot#: LEK-39-01)
・ Dexamethasone (CAS:50-02-2, Fujifilm Wako Pure Chemical Cat#041-18861)
・ Dimethyl sulfoxide (DMSO) (CAS:67-68-5, Sigma Cat#D5879)
・ Distilled water (GIBCO Cat#10977-015)

2-2-3 For measurement of the luciferase activity

・ Tripluc® Luciferase assay reagent (TOYOBO Cat#MRA-301)

2-2-4 Expendable supplies

・ T-75 flask tissue culture treated (e.g., Corning Cat#353136)
・ 96 well black-flame and white-well plate (flat-bottom, for measurement of the luciferase activity, e.g. PerkinElmer B&W Isoplate-96 TC Cat#6005060)
・ 96 well clear plate (round-bottom, for preparation of chemicals and stimulants)
・ 96 well assay block, 2 mL (e.g., Costar Cat#3960)

- Seal for 96 well plate (e.g., Perkin Elmer TopSeal-A PLUS Cat#6050185, EXCEL Scientific SealMate Cat#SM-KIT-SP)
- Reservoir
- Pipette

2-2-5 Equipment for measurement of luciferase activity

- Measuring device: a microplate-type luminometer with a multi-color detection system that can accept an optical filter
  e.g. Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)
- Optical filter: 600 nm long-pass filter, 600～700 nm band-pass filter
- Measuring time: set at 1～5 sec/well measuring time

2-2-6 Others

- Pipetman
- 8 channel or 12 channel pipetman (optimized for 10~100 μL)
- Plate shaker (for 96 well plate)
- CO_2 incubator (37°C, 5% CO_2)
- Water bath
- Cell counter: hemocytometer, trypan blue

2-3 Culture medium

2-3-1A medium: for maintenance of THP-G1b (TGCHAC-A4) cells (500 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO Cat #11875-093	-	-	445 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	50 mL
Antibiotic-Antimycotic	e.g., GIBCO Cat #15240-062	100×	1×	5 mL

2-3-2 B medium: for luciferase assay (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO Cat #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL

2-4 Preparation of the stimulant of THP-G1b (TGCHAC-A4) cells

2-4-1 Lipopolysaccharide (LPS) from Escherichia coli K12

Reagent	Company	Concentration of the stock solution	Final concentration
Lipopolysaccharide (LPS) from Escherichia coli K12	Invivogen Cat#tlrl-eklps	1 mg/mL	100 ng/mL
Distilled water	GIBCO Cat#10977-015		

Dissolve 5 mg LPS using distilled water 5 mL, dispend at 5 μL/tube and store at freezer at -30°C. Use these stocks within 6 months after dissolution.

3. Cell culture

3-1 Thawing of THP-G1b (TGCHAC-A4) cells

Pre-warm 9 mL of A medium in a 15 mL polypropylene conical tube in a 37°C water bath (for centrifugation) and 15 mL of A medium in a T-75 Flask at 37°C in a 5% CO_2 incubator (for culture).

Thaw frozen cells ($2x10^6$ cells / 0.5 mL of freezing medium) in a 37°C water bath, then add to a 15 mL polypropylene conical tube containing 9 mL of pre-warmed A medium. Centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in 15 mL of pre-warmed A medium in a T-75 Flask. Cells are incubated at 37°C, 5% CO_2.

3-2 Maintenance of THP-G1b (TGCHAC-A4) cells

3 or 4 days after thawing, pre-warm the A medium in a T-75 Flask at 37°C in a 5% CO_2 incubator. Count the number of cells, centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in the pre-warmed A medium in a T-75 Flask. Cells are passaged at $2\text{-}5x10^5$/mL, depending on the condition of the cells and incubated at 37°C, 5% CO_2.

The interval between subcultures should be 3~4 days. Cells can be used between one and six weeks after thawing.

4. Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (5.0 x 10^6 cells are required, but to have some leeway, 7.5 x 10^6 cells should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 2×10^6/mL. Transfer the cell suspension to a reservoir, and add 50 µL of cell suspension to each well of a 96 well black-flame and white-well plate (flat bottom) using an 8 channel or 12 channel pipetman. (cf. Figure 2)

5. Preparation of chemicals and cell treatment with chemicals

5-1 Dissolution by vehicle (cf. Figure 3)

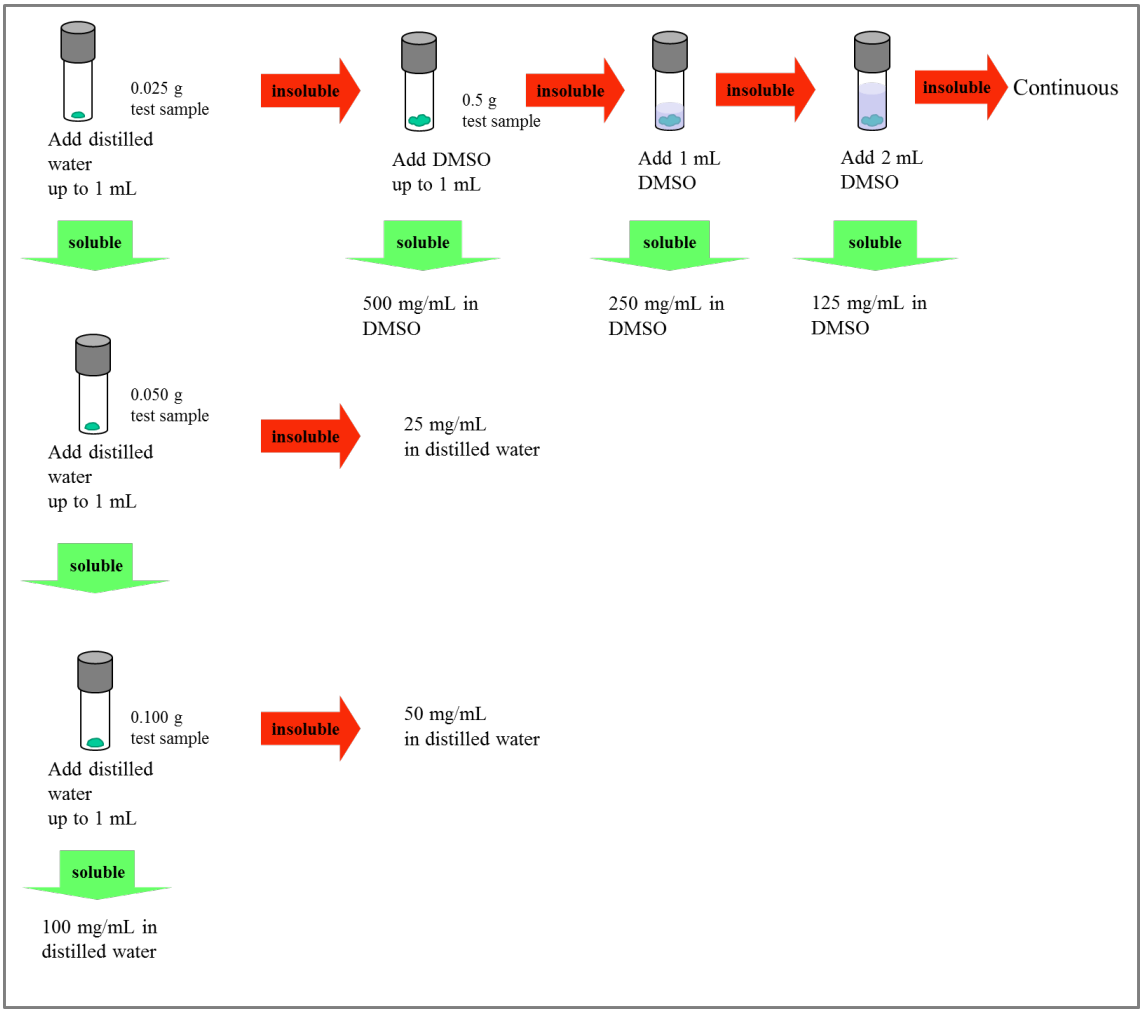
Dissolve the chemical first in distilled water. Namely, weigh 0.025 g of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is soluble at 25 mg/mL, weigh 0.050 g of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is not soluble at 50 mg/mL, 25 mg/mL is the highest soluble concentration. If the chemical is soluble at 50 mg/mL, weigh 0.100 g of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is not soluble at 100 mg/mL, 50 mg/mL is the highest soluble concentration. If the chemical is soluble at 100 mg/mL, 100 mg/mL is the highest soluble concentration.

If the chemical is not soluble in water, the chemical should be dissolved in DMSO at 500 mg/mL. Namely, weigh 0.5 g of the test chemical in volumetric flask and add DMSO up to 1 mL.

If the chemical is not soluble at 500 mg/mL, the highest soluble concentration should be determined by diluting the solution from 500 mg/mL at a common ratio of two (250 mg/mL → 125 mg/mL → continued if needed) with DMSO.

Sonication and vortex may be used if needed, and attempt to dissolve the chemical for at least 5 minutes. Being soluble should be confirmed by centrifugation at 15,000 rpm (≈20,000 x g) for 5 min and absence of precipitation. The chemical should be used within 4 hours after being dissolved in distilled water or DMSO.

Figure 3



In the first experiment (1st experiment), when the chemical is prepared in distilled water, conduct 10 serial dilutions at a common ratio of 2 from the highest concentration using distilled water. When the chemical is prepared as a DMSO solution, conduct 10 serial dilutions at a common ratio of 2 from the highest concentration using DMSO.

In the second to fifth experiment (2nd to 5th experiment), determine the minimum concentration at which I.I.-SLR-LA (mentioned later in **10**) became lower than 0.05 in the 1st experiment, use the concentration one step (2-times) higher than this determined concentration as the highest concentration of the chemical to examine, and conduct 10 serial dilutions at a common ratio of 2 from the highest concentration. If I.I.-SLR-LA did not become lower than 0.05 or became lower than 0.05 at the highest concentration in the 1st experiment, conduct 10 serial dilutions at a common ratio of 2 from the highest concentration in the 1st experiment.

For example, in Figure 3 below, the minimum concentration at which I.I.-SLR-LA became lower than 0.05 is 1.95 μg/ml. The highest concentration of the chemical to examine is the concentration one step (2-times) higher than 1.95 μg/ml, which is 3.91 μg/ml.

In Figure 4 below, I.I.-SLR-LA did not become lower than 0.05. In such a case, the highest concentration of the chemical to examine is the highest concentration in the 1st experiment, namely 125 μg/ml.

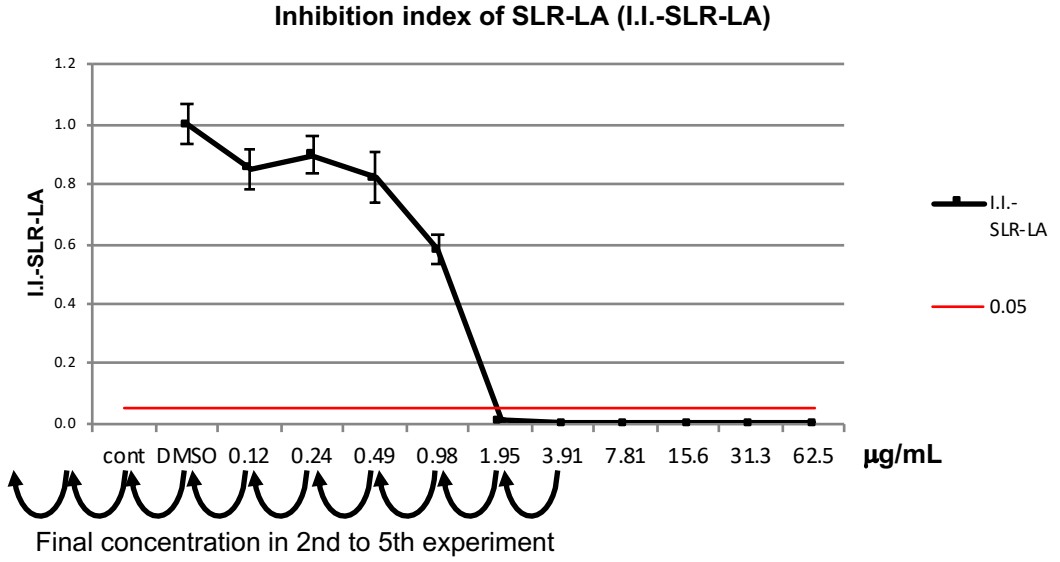


Figure 3.

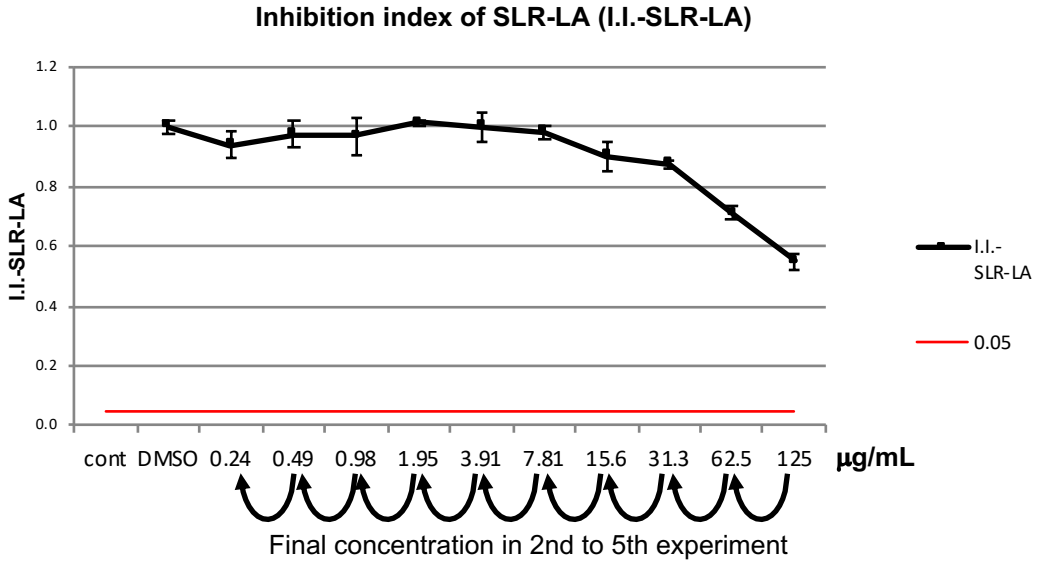

Figure 4

5-2 When the chemical is prepared in distilled water

If the chemical is prepared at a lower concentration, use the prepared concentration instead of the 100 mg/mL distilled water solution.

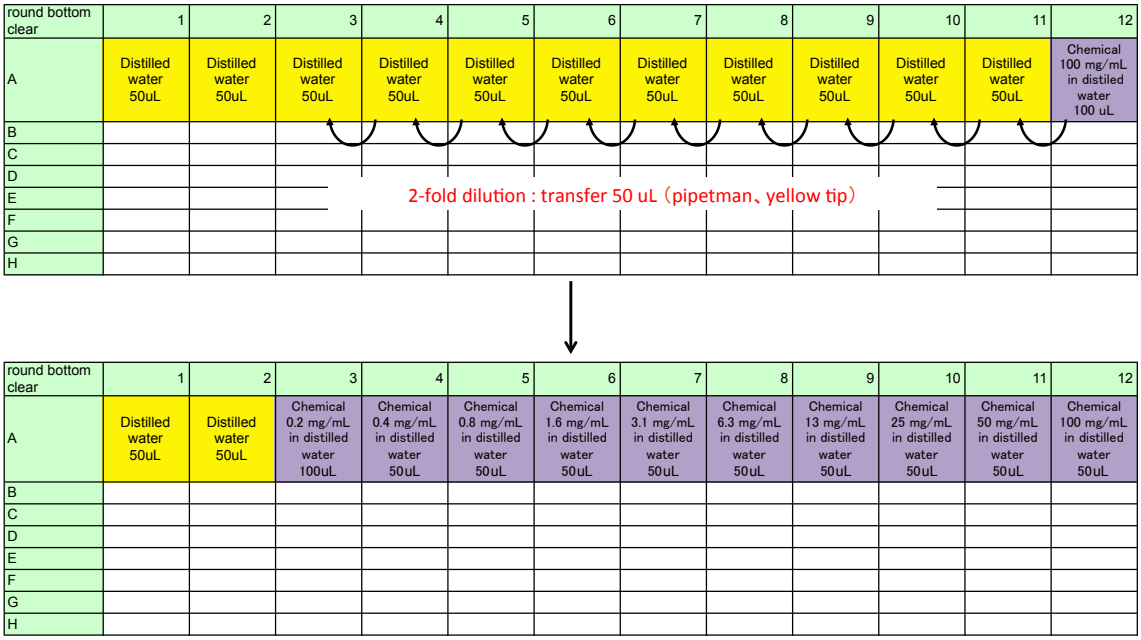
5-2-1 Arrangement of chemicals and vehicle

Add 100 µL of the 100 mg/mL distilled water solution of the chemical to well #A12, and 50 µL of the distilled water to wells #A1-#A11 of the 96 well clear plate (round bottom).

5-2-2 Serial dilution

Conduct 9 serial dilutions at a common ratio of 2 as indicated in Figure 4 from well #A11 to well #A3. Transfer 50 µL to the next (left) well. (cf. Figure 4)

Figure 4



5-2-3　2 step dilution

Add 20 μL of the diluted chemical to 480 μL of the B medium prepared in the assay block. And add 50 μL to THP-G8 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 1 hour (37°C, CO_2, 5%) (cf. Figure 5-7).

5-3 When the chemical is prepared as a DMSO solution

If the chemical is prepared at a lower concentration, use the prepared concentration instead of 500 mg/mL DMSO solution.

5-3-1 Arrangement of chemicals and vehicle

Add 100 µL of the 500 mg/mL DMSO solution of the chemical to well #A12, 50 µL of DMSO to wells #A1-#A11, and 90 µL of the B medium to wells #B1-#B12 of the 96 well clear plate (round bottom)

5-3-2 Serial dilution

Conduct 9 serial dilutions at a common ratio of 2 as indicated in Figure 8 from well #A11 to well #A3. Transfer 50 µL to the next (left) well. (cf. Figure 8)

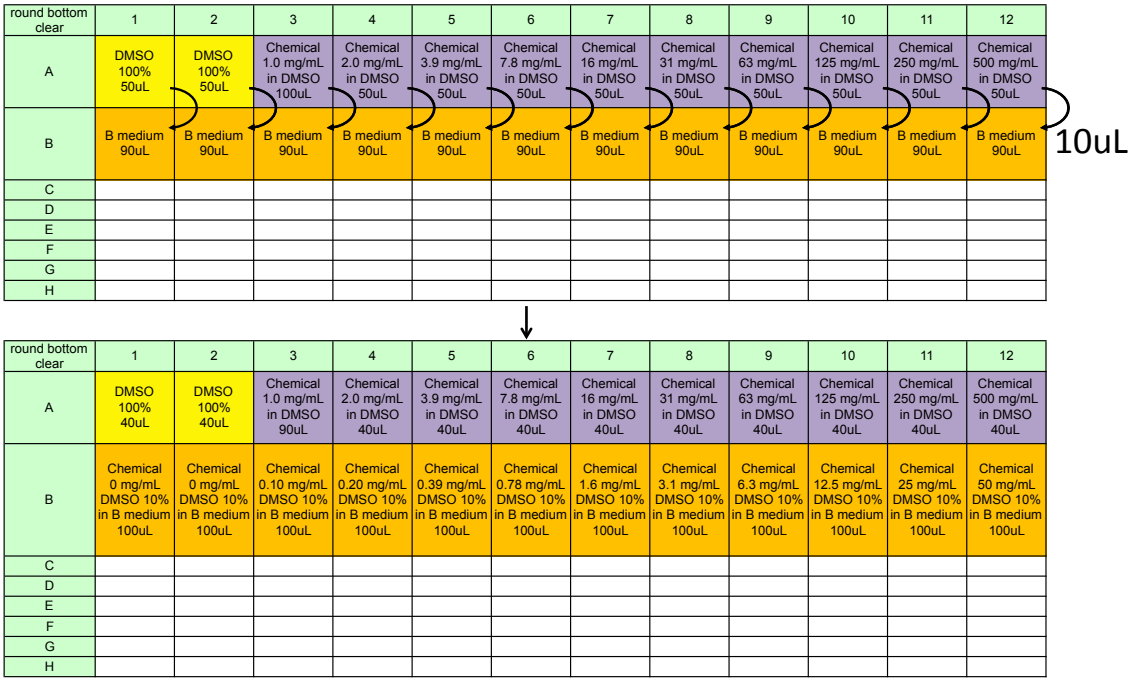
5-3-3 Dilution of DMSO solution with the B medium

Dilute 10 μL of the DMSO solution of the chemical in wells #A1-#A12 with 90 μL of the B medium using an 8-12 channel pipetman. (cf. Figure 9)

Figure 9



5-3-4　2 step dilution

Add 10 µL of the diluted chemical to 490 µL of the B medium prepared in the assay block. And add 50 µL to THP-G8 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Manipulate the procedures from 5-3-3 to 5-3-4 as quickly as you can, and do not leave a long time at step after 5-3-3 or Figure 10. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 1 hour (37°C, CO_2, 5%) (cf. Figure 10-12).

6. Preparation of the stimulant (Lipopolysaccharide (LPS)) and addition to THP-G1b (TGCHAC-A4)

6-1 Material

・ 1 mg/mL LPS stock

6-2 Preparation of 1000 ng/mL LPS solution

Dilute 1 mg/mL LPS stock with distilled water as follows (1000 times, final concentration is 1000 ng/mL). Add distilled water as control to well #A1-#D1 of the 96 well clear plate (round bottom), and add 1000 ng/mL LPS solution to wells #A2-#D2 of the 96 well clear plate (round bottom).

1st step

1 mg/mL LPS	distilled water	Total	final concentration
5 µL	995 µL	1000 µL	5 µg/mL

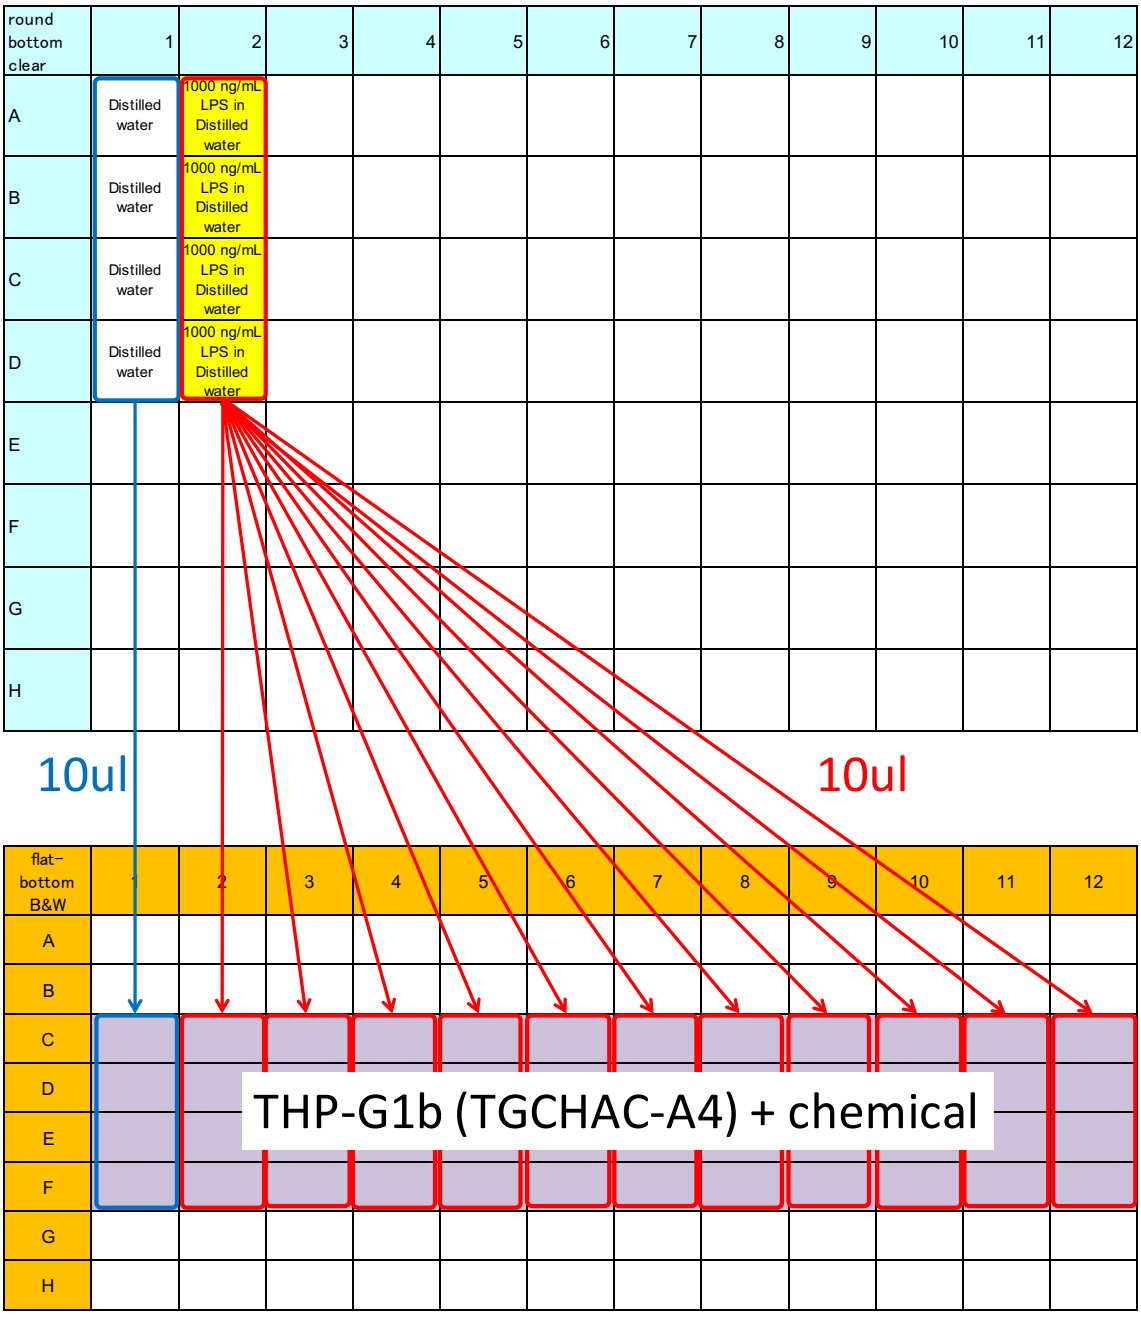
2nd step

5 µg/mL LPS	distilled water	Total	final concentration
250 µL	1000 µL	1250 µL	1000 ng/mL

6-3 Addition of LPS to THP-G1b (TGCHAC-A4)

One hour after the addition of chemicals, add 10 µL of control or 1000 ng/mL LPS solution to the cells (#C1-#F1 or #C2-#F12, respectively) using an 8 channel or 12 channel pipetman after pipetting 20 times. Make sure that the apex of the tip is dipped into the medium. Change tips every line you add. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 6 hours (37°C, CO_2, 5%). (cf. Figure 13)

Figure 13



7. Positive control

7-1 Preparing control chemical (dexamethasone)

7-1-1 Preparing dexamethasone stock

Reagent	Company	Concentration of the stock solution	Preparing concentration	Final concentration
Dexamethasone	Fujifilm Wako Pure Chemical Cat#041-18861	100 mg/mL	10, 50, 100 mg/mL	10, 50, 100 μg/mL
Dimethyl sulfoxide (DMSO)	Sigma Cat#D5879			

Dissolve 1 g of Dexamethasone with DMSO 10 mL, dispend at 100 μL/tube and store at freezer at -30°C.

7-2 Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (2.0 x 10^6 cells are required, but to have some leeway, 3 x 10^6 cells should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 2×10^6/mL. Transfer the cell suspension to a reservoir, and add 50 µL of cell suspension to each well of a 96 well black-flame and white-well plate (flat bottom) using an 8 channel or 12 channel pipetman. (cf. Figure 14)

Figure 14

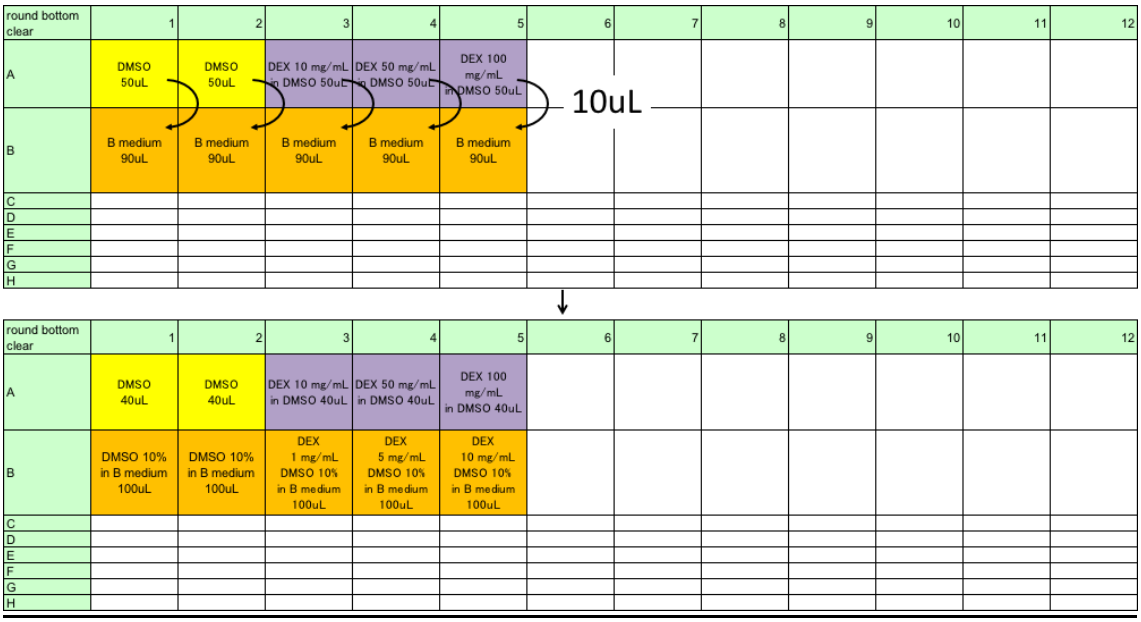
7-3 Arrangement of chemicals and vehicle

Add DMSO 50 µL to #A1-2, 10 mg/mL dexamethasone 50 µl to #A3, 50 mg/mL dexamethasone 50 µl to #A4, 100 mg/mL dexamethasone 50 µl to #A5 and B medium 90 µl to #B1-5 of the 96 well clear plate (round bottom). (cf. Figure 15)

7-4 Dilution with the B medium

Dilute DMSO in #A1-2 and dexamethasone DMSO solution in #A3-5 by adding 10 µL to the B medium in #B1-5. (cf. Figure 15)

Figure 15



7-5　　2 step dilution

Add 10 µL of the diluted DMSO or dexamethasone to 490 µL of the B medium prepared in the assay block. And add 50 µL to THP-G1b (TGCHAC-A4) in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Manipulate the procedures from 7-4 to 7-5 as quickly as you can, and do not leave a long time at step after 7-4 or Figure 16. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 1 hour (37°C, CO_2, 5%). (cf. Figure 16-18)

7-6 Addition of LPS to THP-G1b (TGCHAC-A4)

One hour after the addition of dexamethasone, add 10 µL of distilled water or 1000 ng/mL LPS solution prepared in §6 to the cells (#A1-#D1 or #A2-#D5, respectively) using an 8 channel or 12 channel pipetman after pipetting 20 times. Make sure that the apex of the tip is dipped into the medium. Change tips every line you add. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 6 hours (37°C, CO_2, 5%). (cf. Figure 19)

Figure 19

8. Calculation of the transmittance factors

Color discrimination in multi-color reporter assays is generally achieved using detectors (luminometer and plate reader) equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmittance factors of these filters for each bio-luminescence signal color must be calibrated prior to all experiments by following the protocols below.

8-1 Reagents

- Single reference samples:
  Lyophilized luciferase enzyme reagent for stable luciferase green (SLG)
  Lyophilized luciferase enzyme reagent for stable luciferase red (SLR)
- Assay reagent:
  Tripluc® Luciferase assay reagent（TOYOBO Cat#MRA-301）
- B medium: for luciferase assay (30 mL, stored at 2 – 8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot:715004	-	10 %	3 mL

8-2 Preparation of luminescence reaction solution

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature either in a water bath or at ambient air temperature. Power on the luminometer 30 min before starting the measurement to allow the photomultiplier to stabilize.

Add 200 μL of 100 mM Tris-HCl (pH8.0) contains 10 % glycerol to each tube of lyophilized reference sample to dissolve the enzymes, divide into 10 μL aliquots in 1.5 mL disposable tubes and store in a freezer at -80°C. The stored frozen solution of the reference samples can be used for up to 6 months.

Add 1 mL of the B medium to each tube of frozen reference sample (10 μL sample per tube). Keep the reference samples on ice to prevent deactivation.

8-3 Bioluminescence measurement

Transfer 100 µL of the diluted reference samples to a 96 well black-flame and white-well plate (flat bottom) as shown below (the SLG reference sample to #B1, #B2, #B3, the SLR reference sample to #D1, #D2, #D3).

Figure 20.

flat-bottom B&W	1	2	3	4	5	6	7	8	9	10	11	12
A												
B	SLG 100 µL	SLG 100 µL	SLG 100 µL									
C												
D	SLR 100 µL	SLR 100 µL	SLR 100 µL									
E												
F												
G												
H												

Transfer 100 µL of pre-warmed Tripluc to each well of the plate containing the reference sample using a pipetman. Shake the plate for 10 min at room temperature (about 25°C) using a plate shaker. Remove bubbles in the solutions in wells if they appear. Place the plate in the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1) of the optical filter. An example of the raw output data is shown below.

Figure 21. An example of the raw output data

Measurement without Filter

C												
D	1585258	1420099	1339265									
E												
F												
G												
H												

Two transmittance factors of the optical filter were calculated as follow:

$$\text{Transmittance factor } (\kappa G_{R60}) = \frac{\#B1 \text{ of } F1 + \#B2 \text{ of } F1 + \#B3 \text{ of } F1}{\#B1 \text{ of } F0 + \#B2 \text{ of } F0 + \#B3 \text{ of } F0}$$

$$\text{Transmittance factor } (\kappa R_{R60}) = \frac{\#D1 \text{ of } F2 + \#D2 \text{ of } F2 + \#D3 \text{ of } F2}{\#D1 \text{ of } F0 + \#D2 \text{ of } F0 + \#D3 \text{ of } F0}$$

In the case shown above,

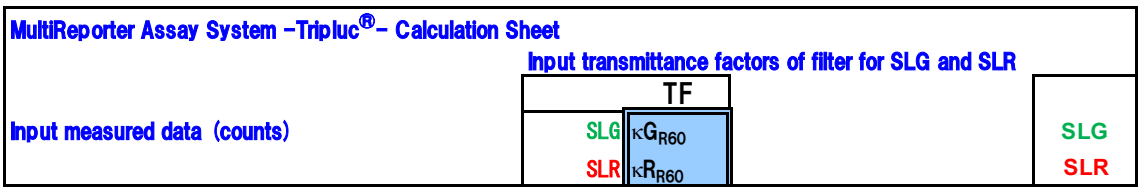
$$\text{Transmittance factors } (\kappa G_{R60}) = \frac{236478+234079+240876}{3757015+3716611+3810382} = 0.063$$

$$\text{Transmittance factors } (\kappa R_{R60}) = \frac{1585258+1420099+1339265}{2465453+2207572+2077689} = 0.644$$

Calculated transmittance factors are used for all the measurements executed using the same luminometer.

Input the transmittance factors to #G4-5 of the “Data Input” sheet of the Data sheet as follow.

Figure 22



9. Measurement

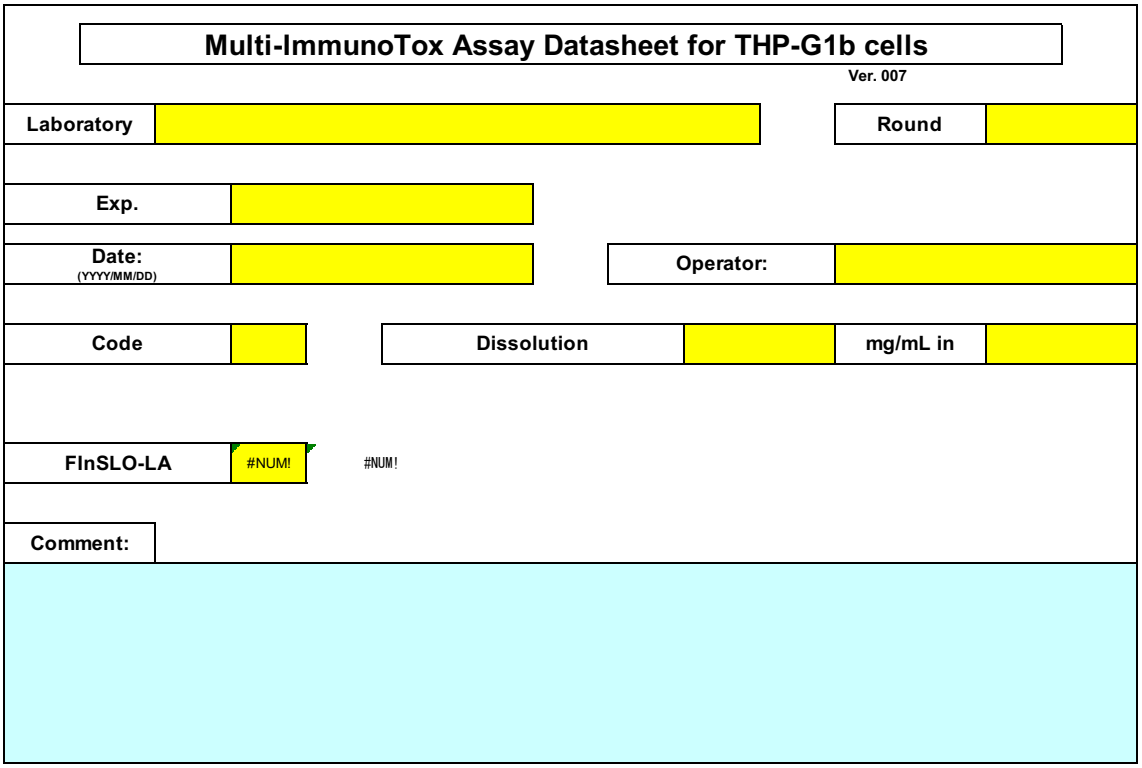
Please refer Appendix 1 for the principle of measurement of luciferase activity.

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature either in a water bath or at ambient air temperature. Power on the luminometer 30 min before starting the measurement to allow the photomultiplier to stabilize.

Transfer 100 μL of pre-warmed Tripluc from the reservoir to each well of the plate containing the reference sample using an 8 channel or 12 channel pipetman. Shake the plate for 10 min at room temperature (about 25°C) using a plate shaker. Remove bubbles in the solutions in the wells if they appear. Place the plate in the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1) of the optical filter. In case alternative settings are used, e.g., depending on the model of luminometer used, these settings should be justified.

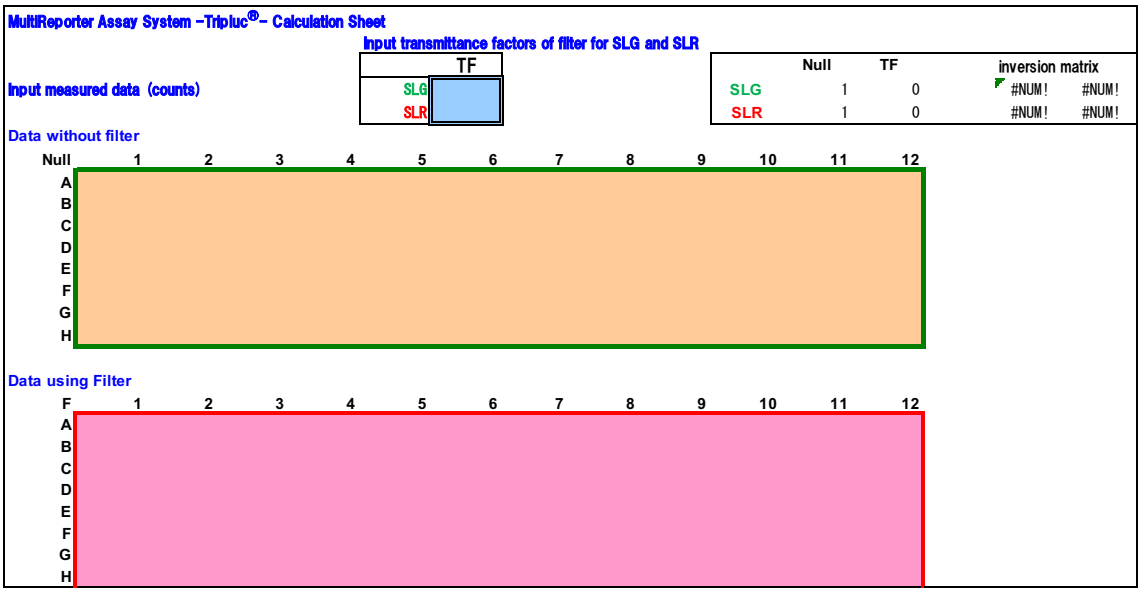
1st. Add the information regarding the name of laboratory, the round of experiments if multiple experimental sets are performed, the experiment number, date, the operator, chemical codes, dissolved in distilled water or DMSO, the prepared concentration and comments if any to Face Sheet of the data sheet.

Figure 23 “Face Sheet” of the data sheet



2nd. Copy the results of the F0 and F1 measurements (values are expressed as counts) and paste them into the appropriate area in the “Data Input” sheet of the data sheet shown below (Figure 28). In addition, input the transmittance factors calculated in chapter 5. Calculation of the transmittance factors to TF of the “Data Input” sheet (Figure 24).

Figure 24 “Data Input” sheet of the data sheet



Next, the calculated results for the parameters of the Multi-Immuno Tox assay for each concentration, e.g., SLG-LA, SLR-LA, nSLG-LA, the mean ± SD of SLG-LA, the mean ± SD of SLR-LA, %suppression and graphs will automatically appear on the “Result Format” sheet of the data sheet.

Figure 25 “Result Format” sheet of the data sheet

10. Data analysis

Definition of the parameters used in the Multi-Immuno Tox assay

- SLG-luciferase activity (SLG-LA): Luciferase activity of stable luciferase orange (Under the control of IL-1β promoter)
- SLR-luciferase activity (SLR-LA): Luciferase activity of stable luciferase red (Under the control of G3PDH promoter)
- Normalized SLG-LA (nSLG-LA): =(SLG-LA)/(SLR-LA)
- Inhibition index of SLR-LA (I.I.-SLR-LA): The cytotoxic effect of chemicals
  =(SLR-LA of THP-G1b treated with chemicals)/(SLR-LA of untreated THP-G1b)
- %suppression: The effect of chemicals on IL-8 promoter
  =(1-(nSLG-LA of THP-G1b treated with chemicals)
  /(nSLG-LA of non-treated THP-G1b)) x 100

11. Criteria

11-1 Acceptance criteria

The following acceptance criteria should be satisfied when using the Multi-Immuno Tox Assay method.

- If Fold induction of nSLG-LA of LPS wells without chemicals (=(nSLG-LA of THP-G1b cells treated with LPS) / (nSLG-LA of non-treated THP-G1b cells)) demonstrate less than 3, the results obtained from the plate containing the control wells should be rejected.
- If the number of concentrations which satisfy I.I.-SLR-LA>=0.05 is less than 6, the experiment, is accepted only when viable wells satisfy the following positive criteria and then, the following experiments should be done using the concentration described in **5-1**.

11-2 Criterion

The experiments are repeated until two consistent positive results or two consistent “non-suppression” are obtained. When two consistent results are obtained, the chemicals are judged as the obtained consistent results.

Identification of immunotoxicant is evaluated by the mean of %suppression and its 95% simultaneous confidence interval.

In each experiment, when the chemicals clear the following 4 criteria, they are judged as suppression. Otherwise, they are judged as non-suppression.
1. The %suppression is ≥ 25 with statistical significance. The statistical significance is judged when the 95% confidence interval does not include 0.
2. The result shows two or more consecutive statistically significant positive data or one statistically significant positive data with a trend in which at least 3 consecutive data increase in a dose dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows the opposite effect without statistical significance.
3. The results are judged using only data obtained in the concentration at which I.I.-SLR-LA is ≥ 0.05
4. The results at 2000 μg/ml is excluded.

The acceptance criteria and the criterion for judgment can be described in the following with the same meaning and possibly more understandable way.

11-1 Acceptance criteria
The following acceptance criteria should be satisfied when using the Multi-ImmunoTox Assay method.

- If Fold induction of nSLG-LA of LPS wells without chemicals (=(nSLG-LA of THP-G1b cells treated with LPS) / (nSLG-LA of non-treated THP-G1b cells)) as a control demonstrates less than 3, the results obtained from the plate containing the control wells should be rejected.
- If the number of concentrations which satisfies I.I.-SLR-LA>=0.05 is less than 6, the experiment is accepted only when viable wells satisfy the following positive criteria and then, the following experiments should be conducted using the concentration described in **5-1**.
- When chemicals are dissolved at 100 mg/ml in water, the data of the wells treated with chemicals at the highest concentration, i.e. 2 mg/ml, was omitted.
-

11-2 Criterion
The experiments are repeated until two consistent suppression or two consistent non-suppression are obtained. When two consistent results are obtained, the chemicals are judged as the obtained consistent results.

Identification of immunotoxicant is evaluated by the %suppression and its 95% confidence interval.

In each experiment, when the chemicals clear the following 3 criteria, they are judged as suppression Otherwise, they are judged as non-suppression.

1. The result shows two or more consecutive statistically significant positive data with $\geq$ 25 of the % suppression or one statistically significant data with $\geq$ 25 of the % suppression and a trend in which at least 3 consecutive data increase in a dose dependent manner. In the latter case, the trend can cross 0, as long as only one data point shows negative data without statistical significance. The statistical significance is judged when the 95% confidence interval does not include 0.
2. The results are judged using only data obtained in the concentration at which I.I.-SLR-LA is $\geq$ 0.05

Appendix 7 Principle of measurement of luciferase activity

MultiReporter Assay System -Tripluc- can be used with a microplate-type luminometer with a multi-color detection system, which can equip an optical filter. (e.g. Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)) The optical filter used in measurement is 600 ～ 620 nm long or short pass filter, or 600～700 nm band pass filter.

(1) Measurement of two-color luciferases with an optical filter.

This is an example using Phelios AB-2350 (ATTO). This luminometer equips a 600 nm long pass filter (600 nm LP (Filter 1); R60 HOYA Co.), for splitting SLG and SLR luminescence.

To determine transmission coefficients of the 600 nm LP, first, using purified SLG and SLR luciferase enzymes, measure i) the intensity of SLG and SLR bioluminescence intensity without filter (F0), ii) the SLG and SLR bioluminescence intensity that passed through 600 nm LP (Filter 1), and calculate the transmission coefficients of 600 nm LP for SLG and SLR listed below.

Transmission coefficients		Abbreviation	Definition
SLG	Filter 1 Transmission coefficients	κG_{R60}	The filter's transmission coefficient for the SLG
SLR	Filter 1 Transmission coefficients	κR_{R60}	The filter's transmission coefficient for the SLR

When the intensity of SLG and SLR in test sample are defined as G and R, respectively, i) the intensity of light without filter (all optical): F0 and ii) the intensity of 600 nm LP (Filter 1) transmitted light are described as below.

$F0=G+R$

$F1=\kappa G_{R60} \times G + \kappa R_{R60} \times R$

These formulas can be rephrased as follows

$$\begin{pmatrix} F0 \\ F1 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ \kappa G_{R60} & \kappa R_{R60} \end{pmatrix} \begin{pmatrix} G \\ R \end{pmatrix}$$

Then using calculated coefficient factors (κG_{R60} and κR_{R60}) and measured F0 and F1, you can calculate G and R-value as follows.

$$\begin{pmatrix} G \\ R \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ \kappa G_{R60} & \kappa R_{R60} \end{pmatrix}^{-1} \begin{pmatrix} F0 \\ F1 \end{pmatrix}$$

This calculation can be performed using the functions "MININVERSE" and "MMULT" in Microsoft Excel. These calculations are integrated in the Data sheet for MITA THP-G1b.

Appendix 8 Validation of reagents and equipment

1 Measurement of transmittance of optical filter for multicolor measurement

For color discriminations in the multi-color reporter assay, detectors (luminometer and plate reader) are usually equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmittance factors of these filters for each bioluminescence signal color have to be calibrated prior to all experiments by following the protocols below.

1-1 Reagents

・Single reference samples:

Lyophilized luciferase enzyme reagent of SLG

Lyophilized luciferase enzyme reagent of SLR

・Assay reagent:

Tripluc® Luciferase assay reagent（TOYOBO Cat#MRA-301）

・B medium: for luciferase assay (30 mL, stored at 2−8°C)

Reagent	Company		Final conc. in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1E Lot: 715004	-	10 %	3 mL

1-2 Calibration

1-2-1 Preparation of luminescence reaction solution

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature by bathing in water or ambient air. Start the luminometer 30 min before starting the measurement for stabilization of the photomultiplier.

Add 200 μL of 100 mM Tris-HCl (pH8.0) contains 10% glycerol to each tube of the lyophilized reference samples to dissolve the enzymes, followed by separating them into 1.5 mL disposable tubes at 10 μL each and storing in a freezer at -80°C. The stored frozen solution of the reference samples can be used for one half year.

Add 1 mL of B medium to each tube of the frozen reference sample (10 μL in a tube) and label them as SLG1/1, SLR1/1, and SLG/SLR1/1. Keep the reference samples on ice to prevent deactivation.

Prepare dilution series of the single reference samples of SLG and SLR as follows. Dilute 0.3 mL of each 1/1 solution with 0.9 mL of B medium to make SLG1/4 and SLR1/4. In the same manner, prepare 1/16 and 1/64 solution of each. Keep diluted reference samples on ice.

1-2-2 Bioluminescence measurement

Transfer 100 μL of the diluted reference samples to a 96-well flat-bottom black plate as shown below.

Figure 26.

E												
F												
G												
H												

Transfer 100 μL of pre-warmed Tripluc to each well containing the reference samples of the plate using a pipetman. Shake the plate for 10 min at room temperature (about 20°C) with a plate shaker. Remove bubbles on the solutions in wells if they appear. Place the plate into the luminometer of the under-test to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1) of the optical filter. The example of the raw output data was shown below.

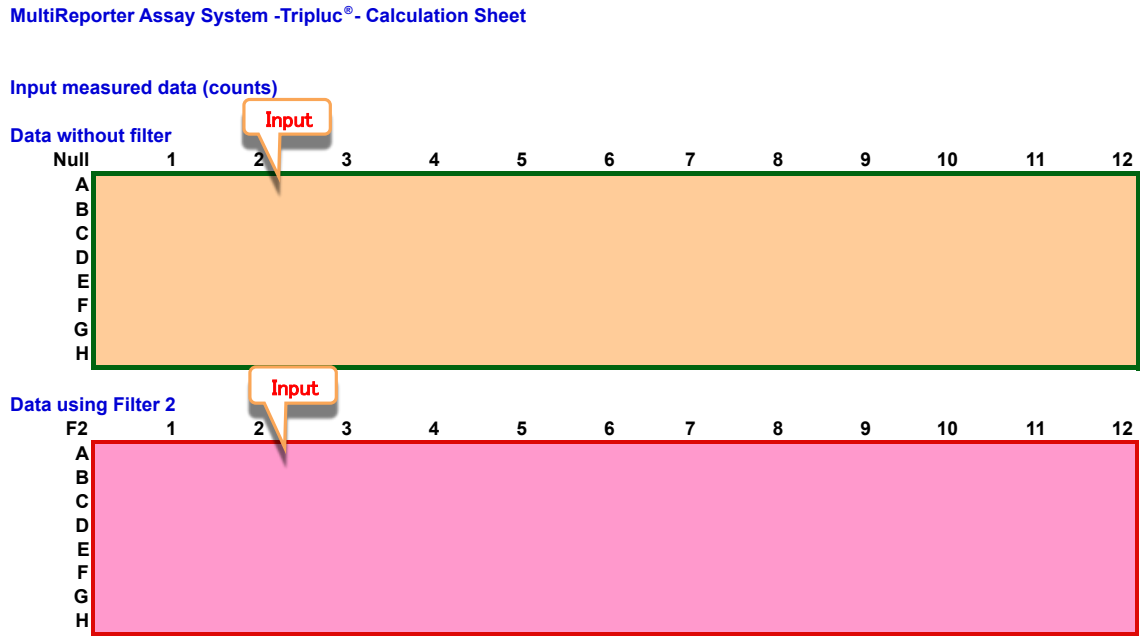
Copy the results of the F0 and F1 measurement (values are expressed as counts) and paste it to the appropriate area in the “Data Input” sheet of the data sheet for data analyses shown below.

Figure 33.



Record all the results for quality control.

2 Quality control of equipment

In order to confirm the detector stability as the quality control, the reference luciferase sample, optical property, the protocol described hereafter should be performed at the beginning of the experiments every day using reference LED light source plates equipped

with stabilized LEDs. LED plate data typically fluctuates up to 1.5% (σ). Disagreement to the old data should be less than 3×σ (= 4.5%). Here describes an example using a commercially available reference light source, TRIANT® (wSL-0001) by ATTO (Tokyo, Japan).

Start LED plate and select “PMT” mode.

Select three-color (BRG) mode and adjust light intensity to 1/10 (10E-1).

Place the LED plate into the luminometer. Light intensity is measured for 3 sec each in the absence (F0) and presence (F2) of the optical filter.

Read and record the data at the position of #F6, #E6, and #D6 that are LEDs of blue, green, and red LEDs, respectively.

LED plate data typically fluctuates up to 1.5% (σ). Disagreement to the old data should be less than 3×σ (= 4.5%).

Red character: Data for cytokine expression or production after LPS stimulation.

Quality assurance report for IL-1β validation study

Hajime Kojima and Asako Ueda

JaCVAM, NIHS

2020.3.31

１． Chemical distribution

1-1. Chemical Acquisition, Coding and Distribution

The assessment of laboratory transferability, and within- and between-laboratory reproducibility and predictivity, in all test facilities were performed with the coded chemicals. The coding was supervised by JaCVAM (See Appendix 1). JaCVAM was responsible for coding and distributing the test chemicals for the validation study.

1-2. Handling

The chemical master at each test facility received complete information considered essential regarding the test chemicals (physical state, weight or volume of sample, specific density for liquid test chemicals, and storage instructions) by JaCVAM. Moreover, the test facility chemical master stored each chemical at conditions in accordance with the storage instructions and received sealed safety information such as the Material Safety Data Sheet (MSDS) describing the hazards identification and exposure controls/personal protection for each chemical (See Appendix 2.1 and 2.2). The test chemicals were delivered directly to the study director and the study director was not shown the MSDSs. The study director was to refer to the MSDSs only in the event of an accident. If the study director referred to the MSDS, he/she was not to reveal the content of the MSDS to the test facility technicians.

No accidents occurred during the course of the validation study, and all test facilities returned the MSDSs for the test chemicals to JaCVAM in their sealed envelope upon completion of the validation study. All test chemicals were disposed of in compliance with the rules and regulations of the test facilities upon completion of the validation study.

２． Quality assurance

All the records (data sheets and record sheets) from the participating laboratories were checked by Dr. Takashi Omori, Kobe univ. and JaCVAM (See Appendix 3). The record sheets mean “Reagent records, solubility test, Cell culture records, Test records and data sheets”. They are total more than 300 pages and available at JaCVAM website (http:// http://www.jacvam.jp/validation08-login.html). Testings performed as part of a validation study were carried out in accordance with the principles of GLP (OECD, 1998) and necessarily include, without being limited to, the use of protocol and adequate recording of data as well as suitable reporting of results and archival record keeping.

The culture of the cells, the preparation and application of test chemicals and data sheets were completed and the results accurately reflect the raw data. Unfortunately, the record sheets on the maintenance of measuring instruments had not collected before the

validation study. JaCVAM considered these records had concerns on quality of data in the validation study. However, JaCVAM checked carefully all the results and judged all data within acceptable ranges.

At least, the reliability of measuring instruments would be checked by an independent organization before the validation study. JaCVAM recommend the validation management team the formal validation study participated with GLP laboratories will be done.

Appendix 18. The list of proficiency chemicals

The list of proficiency chemicals

No.	Chemical name	CAS No.	Immunotoxicity	Physical state	Phase
1	Dexamethasone	50-02-2	Yes	Solid	positive control
2	Dibutyl phthalate	84-74-2	Yes	Liquid	I
3	Perfluorooctanois acid	335-67-1	Yes	Solid	II
4	Citral	5392-40-5	Yes	Liquid	II
5	Trichloroethylene	79-01-6	No	Liquid	II
6	Mannitol	69-65-8	No	Solid	II

Prior to routine use of the test method described in this Annex to Test Guideline 442E, laboratories should demonstrate technical proficiency, using the 6 Proficiency Substances listed in Appendix 15 in compliance with the Good in vitro Method Practices (1). Moreover, test method users should maintain a historical database of data generated with the reactivity checks (see paragraph 15) and with the positive and solvent/vehicle controls (see paragraphs 21-24), and use these data to confirm the reproducibility of the test method in their laboratory is maintained over time.

13	Sodium chlorite	7758-19-2	negative	Solid	II	P
14	5-Nitro-2-furaldehydesemicarbazone	59-87-0	negative	Solid	II	N
15	Trichloroethylene	79-01-6	negative	Liquid	II	N
16	D(-)-Mannitol	69-65-8	negative	Solid	II	N

Performance standards (PS) are shown to facilitate the validation of modified *in vitro* IL-2 luciferase test methods similar to the IL-2 Luc assay and allow for timely amendment of this Test Guideline for their inclusion. Mutual Acceptance of Data (MAD) will only be guaranteed for test methods validated according to the PS, if these test methods have been reviewed and included in this Test Guideline by the OECD.

1. Introduction

The IL-2 Luc leukocyte toxicity test (IL-2 Luc LTT) is aimed to detect immunosuppressive chemicals the mechanism of which is mostly due to suppression of cell proliferation. The IL-2 Luc LTT protocol is similar to that of the IL-2 Luc assay established previously, except for the duration of chemistry and cell seeding concentration.

(Kimura Y. et al. Evaluation of the Multi-Immuno Tox Assay composed of 3 human cytokine reporter cells by examining immunological effects of drugs *Toxicol in Vitro*, 28, 759-768, 2014)

2. Materials

2-1 Cells

・/ 2H4 (IL2-SLG, IFNγ-SLO, G3PDH-SLR)

A Jurkat-derived IL-2 and IFNγ reporter cell line, 2H4, that harbors the SLG, SLO and SLR luciferase genes under the control of the IL-2, IFNγ and GAPDH promoters, respectively, was established by Tsuruga Institute of Biotechnology, TOYOBO Co. Ltd.

(Saito R. et al. Nickel differentially regulates NFAT and NF-κB activation in T cell signaling *Toxicology and Applied Pharmacology*, 254, 245–255, 2011)

2-2 Reagents and equipment

2-2-1 For maintenance of the 2H4 cells

・/ RPMI-1640 (GIBCO Cat#11875-093, 500 mL)
・/ FBS (Biological Industries Cat#04-001-1A Lot: 1524129)
・/ Antibiotic-Antimycotic (GIBCO Cat#15240-062)
・/ HygromycinB (CAS:31282-04-9, Invitrogen Cat#10687-010)
・/ G418 (CAS:108321-42-2, WAKO Cat#071-06431)
・/ Puromycin (CAS:58-58-2, InvivoGen Cat#ant-pr-1)

2-2-2 For chemical exposure, stimulation and solvents

・/ Ionomycin (CAS:56092-82-1, Sigma Cat#I0634)
・/ Phorbol 12-myristate 13-acetate (PMA) (CAS:16561-29-8, Sigma Cat#P8139)
・/ Ethanol (e.g., Wako Cat#057-00456)
・/ Dimethyl sulfoxide (DMSO) (CAS:67-68-5, Sigma Cat#D5879)
・/ Distilled water (GIBCO Cat#10977-015)

2-2-3 For measurement of the luciferase activity

・/ Tripluc® Luciferase assay reagent (TOYOBO Cat#MRA-301)

2-2-4 Expendable supplies

・/ T-75 flask tissue culture treated (e.g., Corning Cat#353136)
・/ 96 well μclear black plate (flat-bottom, for measurement of the luciferase activity, e.g. Greiner Bio-one Cat#655090)
・/ 96 well clear plate (round-bottom, for preparation of chemicals and stimulants)
・/ 96 well assay block, 2 mL (e.g., Costar Cat#3960)
・/ Seal for 96 well plate (e.g., Perkin Elmer TopSeal-A PLUS Cat#6050185, EXCEL

Scientific SealMate Cat#SM-KIT-SP)

・/ Reservoir

・/ Pipette

2-2-5 Equipment for measurement of luciferase activity

・/ Measuring device: a microplate-type luminometer with a multi-color detection system that can accept two optical filter
e.g. Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)

・/ Optical filter: 560 nm long-pass filter and 600 nm long-pass filter

・/ Measuring time: set at 1〜5 sec/well measuring time

2-2-6 Others

・/ Pipetman

・/ 8 channel or 12 channel pipetman (optimized for 10~100 μL)

・/ Plate shaker (for 96 well plate)

・/ CO_2 incubator (37°C, 5% CO_2)

・/ Water bath

・/ Cell counter: hemocytometer, trypan blue

2-3 Culture medium

2-3-1 A medium: for maintenance of 2H4 cells (500 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	440 mL
FBS	Biological Industries Cat#04-001-1A Lot: 1524129	-	10 %	50 mL
Antibiotic-Antimycotic	GIBCO #15240-062	100×	1×	5 mL
Puromycin	InvivoGen # ant-pr-1	10 mg/mL	0.15 μg/mL	7.5 μL
G418	WAKO Cat#071-06431	50 mg/mL	300 μg/mL	3 mL
HygromycinB	Invitrogen #10687-010	50 mg/mL	200 μg/mL	2 mL

2-3-2 B medium: for luciferase assay (30 mL, stored at 2-8°C)/

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1A Lot: 1524129	-	10 %	3 mL

2-3-3 C medium: for thawing 2H4 cells (30 mL, stored at 2-8°C)

Reagent	Company	Concentration	Final concentration in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	26.7 mL
FBS	Biological Industries Cat#04-001-1A Lot: 1524129	-	10 %	3 mL
Antibiotic-Antimycotic	GIBCO #15240-062	100×	1×	0.3 mL

2-4 Preparation of the stimulant of 2H4

2-4-1 Phorbol 12-myristate 13-acetate (PMA)

Reagent	Company	Concentration of the stock solution	Final concentration
Phorbol 12-myristate 13-acetate (PMA)	Sigma #P8139	2 mM	25 nM
DMSO	Sigma #D5789		

Dissolve 1 mg PMA using DMSO 811 μL, dispend at 5 μL/tube and store at freezer at -30°C. Use these stocks within 6 months after dissolution.

2-4-2 Ionomycin

Reagent	Company	Concentration of the stock solution	Final concentration
Ionomycin	Sigma # I0634	2 mM	1 μM
Ethanol	Wako #057-00456		

Dissolve 1mg Ionomycin using ethanol 669.3 μL, dispend at 15 μL/tube and store at freezer at -30°C. Use these stocks within 6 months after dissolution.

3. Cell culture

3-1 Thawing of 2H4 cells

Pre-warm 9 mL of C medium in a 15 mL polypropylene conical tube in a 37°C water bath (for centrifugation) and 15 mL of C medium in a T-75 Flask at 37°C in a 5% CO_2 incubator (for culture).

Thaw frozen cells ($5x10^6$ cells / 0.5 mL of freezing medium) in a 37°C water bath, then add to a 15 mL polypropylene conical tube containing 9 mL of pre-warmed C medium. Centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in 15 mL of pre-warmed C medium in a T-75 Flask. Cells are incubated at 37°C, 5% CO_2.

3-2 Maintenance of 2H4 cells

Pre-warm the A medium in a T-75 Flask at 37°C in a 5% CO_2 incubator. The culture medium should be changed to the A medium 3 or 4 days after thawing. At that time, count the number of cells, centrifuge the tube at 120-350 x *g* at room temperature for 5 min, discard the supernatant, and resuspend in pre-warmed the A medium in a T-75 Flask. Cells are passaged at $1\sim3x10^5$/mL and incubated at 37°C, 5% CO_2.

The interval between subcultures should be 3~4 days. Cells can be used between one and six weeks after thawing.

4. Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (1.0 x 10^6 cells for two chemicals are required, but to have some leeway, 1.5 x 10^6 for two chemicals should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 2 x 10^5/mL. Transfer the cell suspension to a reservoir, and add 50 µL of cell suspension to each well of a 96 well µclear black plate (flat bottom) using an 8 channel or 12 channel pipetman. (cf. Figure 2)

5. Preparation of chemicals and cell treatment with chemicals

5-1 Dissolution by vehicle

Dissolve the chemical first in distilled water. Weigh 10 mg of the test chemical in a volumetric flask and add distilled water up to 1 mL. If the chemical is soluble at 10 mg/mL, use 10 mg/ml solution for the stock solution.

If the chemical is not soluble at 10 mg/ml in water, the chemical should be dissolved in DMSO at 200 mg/mL. For example, weigh 200 mg of the test chemical in volumetric flask and add DMSO up to 1 mL. (cf. Figure 3). If the chemical does not dissolve in DMSO at 200 mg/ml, use the highest concentration possible after diluting with DMSO at a dilution factor of 2.

For expensive chemicals, prepare the highest concentration possible instead of 10 mg/mL distilled water. If the chemical is not soluble, prepare the highest concentration possible in DMSO.

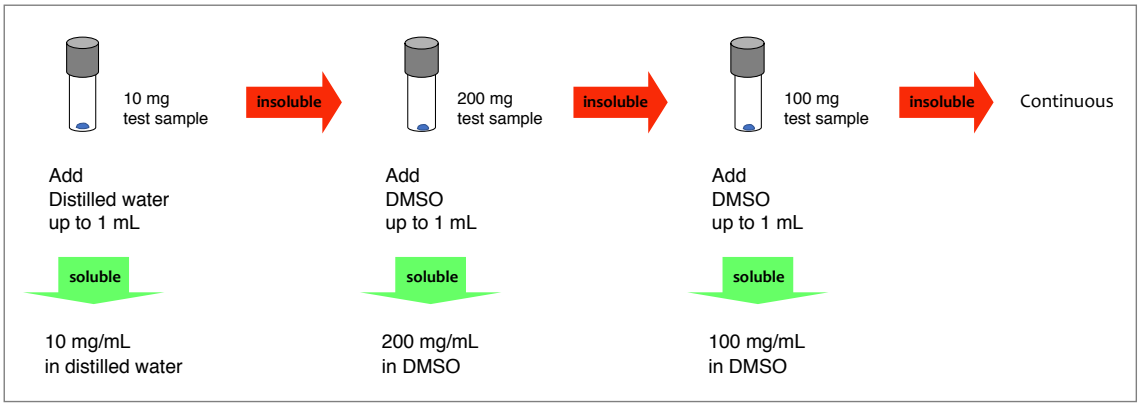
Sonication and vortex may be used if needed, and attempt to dissolve the chemical for at least 5 minutes. Being soluble should be confirmed by centrifugation at 15,000 rpm (≈20,000 x g) for 5 min and confirm the absence of precipitation. The chemical should be used within 4 hours after being dissolved in distilled water or DMSO.

In the first experiment (1st experiment), when the chemical is prepared in distilled water, conduct 10 serial dilutions at a dilution factor of 2 from the highest concentration using distilled water. When the chemical is prepared as a DMSO solution, conduct 10 serial dilutions at a dilution factor of 2 from the highest concentration using DMSO.

In the second and third experiment (2nd and 3rd experiment), determine the minimum concentration at which Inh-GAPLA (mentioned later in **10**) becomes lower than 0.05 in the 1st experiment, use the concentration one step (2-times) higher than this determined concentration as the highest concentration of the chemical to examine, and conduct 10 serial dilutions at a dilution factor of 2 from the highest concentration. (cf. Figure 4) If Inh-GAPLA did not become lower than 0.05 or became lower than 0.05 at the highest concentration in the 1st experiment, conduct 10 serial dilutions at a dilution factor of 2 from the highest concentration in the 1st experiment. (cf. Figure 5)

In addition, if the chemical gives Inh-GAPLA < 0.7 at the lowest concentration and does not give significant reduction of Inh-GAPLA at the higher concentrations, use the concentration two step (4-times) higher than the lowest concentration in the first experiment as the highest concentration of the chemical to examine (cf. Figure 6).

Figure 3



For example, in Figure 4 below, the minimum concentration at which Inh-GAPLA becomes lower than 0.05 is 6.25 μg/ml. The highest concentration of the chemical to examine is the concentration one step (2-times) higher than 6.25 μg/ml, which is 12.5 μg/ml.

In Figure 5 below, Inh-GAPLA does not become lower than 0.05. In such a case, the highest concentration of the chemical to examine is the highest concentration in the 1st experiment, namely 25 μg/ml.

In Figure 6 below, since the chemical gives Inh-GAPLA < 0.7 at the lowest concentration and does not give significant reduction of Inh-GAPLA at the higher concentrations, use the concentration two step (4-times) higher than the lowest concentration (0.39 μg/ml) in the first experiment as the highest concentration of the chemical to examine, which is 1.56 μg/ml.

Figure 4

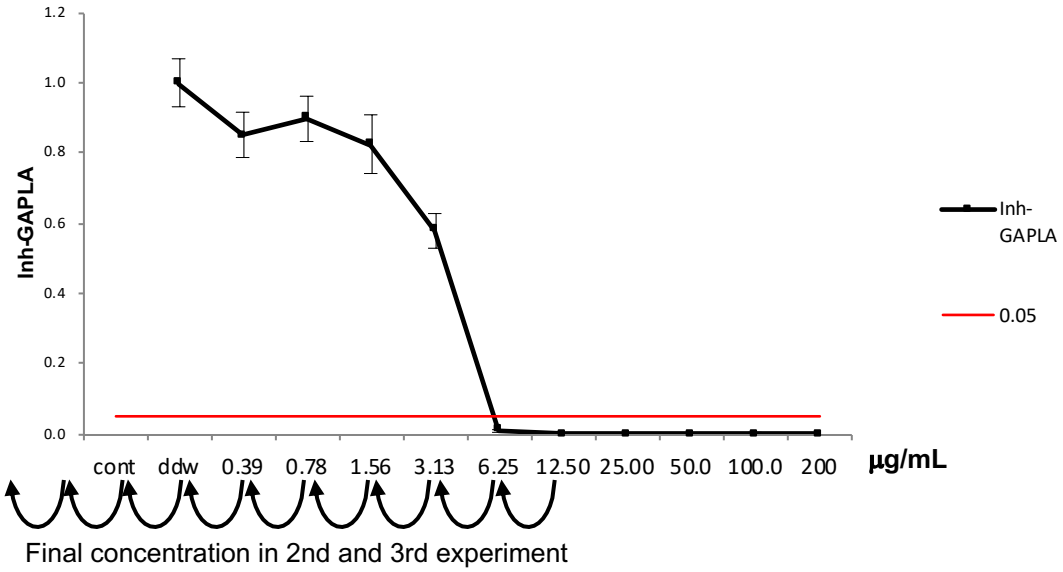


Figure 5

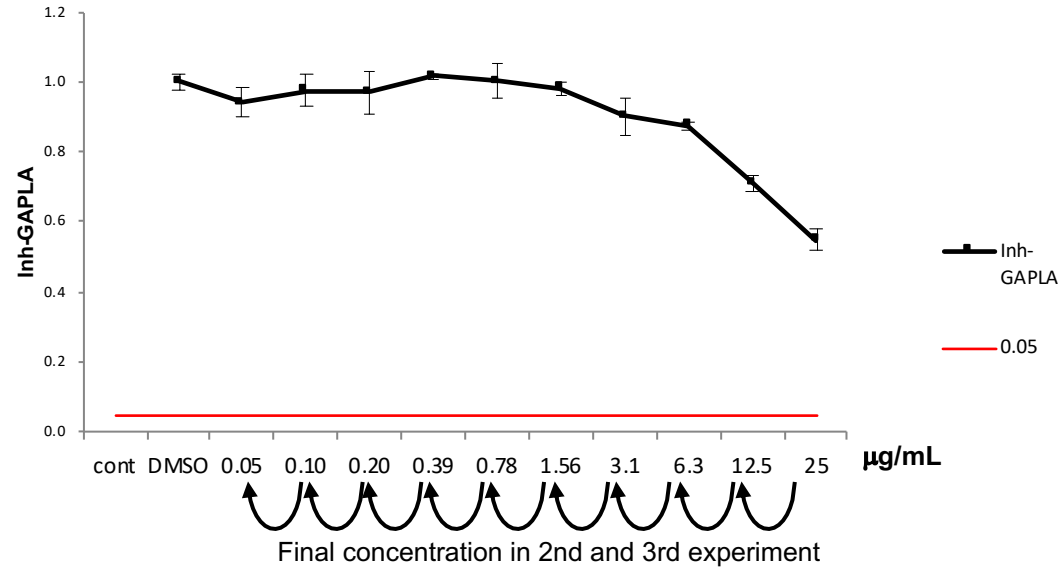

Figure 6

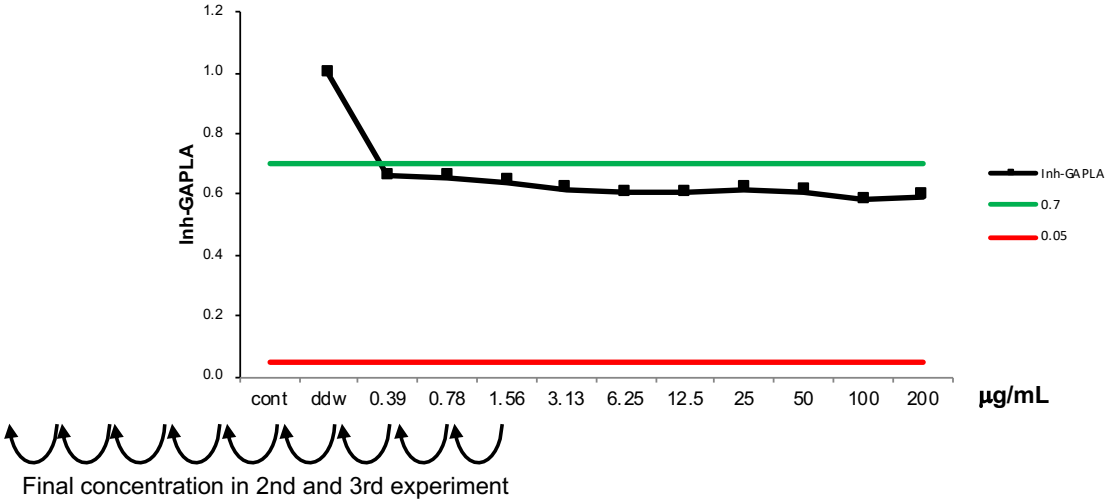

Final concentration in 2nd and 3rd experiment

5-2 When the chemical is prepared in distilled water

If the chemical is prepared at a lower concentration, use the prepared concentration instead of the 10 mg/mL distilled water solution.

5-2-1 Arrangement of chemicals and vehicle

Add 100 μL of the 10 mg/mL distilled water solution of the chemical to well #A12, and 50 μL of the distilled water to wells #A1-#A11 of the 96 well clear plate (round bottom).

5-2-2 Serial dilution

Conduct 9 serial dilutions at a common ratio of 2 as indicated in Figure 4 from well #A11 to well #A3. Transfer 50 μL to the next (left) well. (cf. Figure 7)

Figure 7

5-2-3 2 step dilution

Add 20 μL of the diluted chemical to 480 μL of the B medium prepared in the assay block. And add 50 μL to 2H4 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 24 hours (37°C, CO_2, 5%) (cf. Figure 8-10).

5-3 When the chemical is prepared as a DMSO solution

If the chemical is prepared at a lower concentration, use the prepared concentration instead of 200 mg/mL DMSO solution.

5-3-1 Arrangement of chemicals and vehicle

Add 100 μL of the 200 mg/mL DMSO solution of the chemical to well #A12, 50 μL of DMSO to wells #A1-#A11, and 90 μL of the B medium to wells #B1-#B12 of the 96 well clear plate (round bottom)

5-3-2 Serial dilution// / / / /

Conduct 9 serial dilutions at a common ratio of 2 as indicated in Figure 8 from well #A11 to well #A3. Transfer 50 μL to the next (left) well. (cf. Figure 11)

5-3-4　2 step dilution

Add 10 μL of the diluted chemical to 490 μL of the B medium prepared in the assay block. And add 50 μL to 2H4 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Manipulate the procedures from 5-3-3 to 5-3-4 as quickly as you can, and do not leave a long time at step after 5-3-3 or Figure 11. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 24 hours (37°C, CO_2, 5%) (cf. Figure 13-15).

6. Preparation of the stimulant (PMA/ionomycin) and addition to 2H4

6-1 Material

・2 mM PMA stock

・2 mM Ionomycin stock

・B medium

・Ethanol

6-2 Preparation of 100 μM PMA

Dilute 2 mM PMA stock with the B medium as follows (20 times, final concentration is 100 μM).

2 mM PMA	B medium	Total	final concentration
5 μL	95 μL	100 μL	100 μM

6-3 Preparation of control and x10 PMA/ionomycin solution

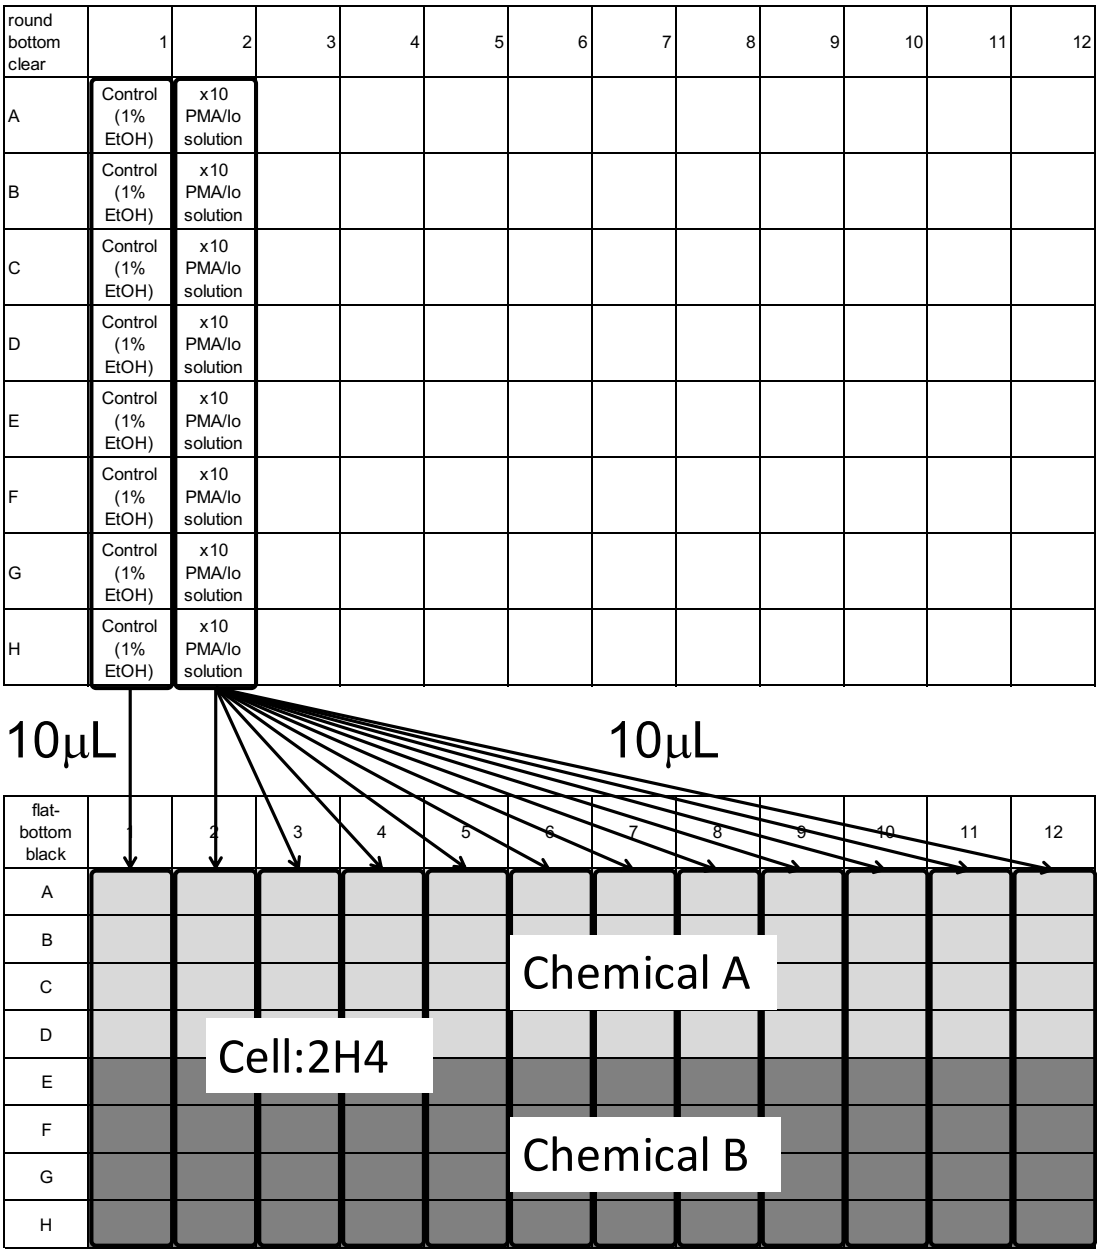
Dilute ethanol, 2 mM ionomycin and 100 μM PMA with the B medium to prepare control or x10 PMA/ionomycin solution. Add the control to well #A1-#H1 of the 96 well clear plate (round bottom), and add x10 PMA/ionomycin solution to wells #A2-#H2 of the 96 well clear plate (round bottom).

	B medium	2 mM Ionomycin	100 μM PMA	Ethanol	Total
Control	995 μL	-		5 μL	1000 μL
x10 PMA/ionomycin solution	2382 μL	12 μL	6 μL	-	2400 μL

6-4 Addition of PMA/ionomycin to 2H4

Twenty-four hours after the addition of chemicals, add 10 μL of control or PMA/ionomycin solution to the cells (#A1-#H1 or #A2-#H12, respectively) using an 8 channel or 12 channel pipetman after pipetting 20 times. Make sure that the apex of the tip is dipped into the medium. Change tips every line you add. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 6 hours (37°C, CO_2, 5%). (cf. Figure 16)

Figure 16



7. Control

7-1 Preparing control chemical (bleomycin sulfate, dexamethasone)

7-1-1 Preparing bleomycin sulfate stock

Reagent	Company	Concentration of the stock solution	Preparing concentration	Final concentration
bleomycin sulfate	TOKYO CHEMICAL INDUSTRY B3972	10 mg/mL	10 mg/mL	0.4~200 μg/mL
Distilled water	GIBCO Cat#10977-015			

Dissolve 10 mg of bleomycin sulfate with distilled water 1 mL, dispend at 100 μL/tube and store a freezer at -30°C.

7-1-2 Preparing dexamethasone stock

Reagent	Company	Concentration of the stock solution	Preparing concentration	Final concentration
dexamethasone	Wako 041-18861	500 mg/mL	500 mg/mL	1.0~500 μg/mL
DMSO	Sigma #D5789			

Weigh 1 g of dexamethasone in volumetric flask and add DMSO up to 2 mL, dispend at 100 μL/tube and store a freezer at -30°C.

7-2 Preparation of cells for assay

A cell passage should be done 2-4 days before the assay.

Use cells between 1 and 6 weeks after thawing.

Pre-warm the B medium in a 37°C water bath. Count the number of cells and collect the number of cells needed (1.0 x 10^6 for two chemicals are required, but to have some leeway, 1.5 x 10^6 for two controls should be prepared), centrifuge the tube at 120-350 x *g*, 5 min. Resuspend in pre-warmed the B medium at a cell density of 2 x 10^5/mL. Transfer the cell suspension to a reservoir, and add 50 µL of cell suspension to each well of a 96 well µclear black plate (flat bottom) using an 8 channel or 12 channel pipetman. (cf. Figure 17)

7-3 Arrangement of chemicals and vehicle

Add 100 μL of the 10 mg/mL distilled water solution of bleomycin sulfate to well #A12, and 50 μL of the distilled water to wells #A1-#A11 of the 96 well clear plate (round bottom).

Add 100 μL of the 500 mg/mL DMSO solution of dexamethasone to well #E12, 50 μL of DMSO to wells #E1-#E11, and 90 μL of the B medium to wells #F1-#F12 of the 96 well clear plate (round bottom)

7-4 Serial dilution

Conduct 9 serial dilutions at a common ratio of 2 as indicated in Figure 17 from well #A11 to well #A3 and #E11 to well #E3. Transfer 50 μL to the next (left) well. (cf. Figure 18)

7-6 Dilution of DMSO solution with the B medium

Dilute 10 μL of the DMSO solution of dexamethasone in wells #E1-#E12 with 90 μL of the B medium using an 8-12 channel pipetman. (cf. Figure 21)

7-7 2 step dilution

Add 10 μL of the diluted dexamethasone to 490 μL of the B medium prepared in the assay block. And add 50 μL to 2H4 in a 96 well plate using an 8 channel or 12 channel pipetman after pipetting 20 times. Manipulate the procedures from 7-6 to 7-7 as quickly as you can, and do not leave a long time at step after 7-6 or Figure 20. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 24 hours (37°C, CO_2, 5%). (cf. Figure 22-24).

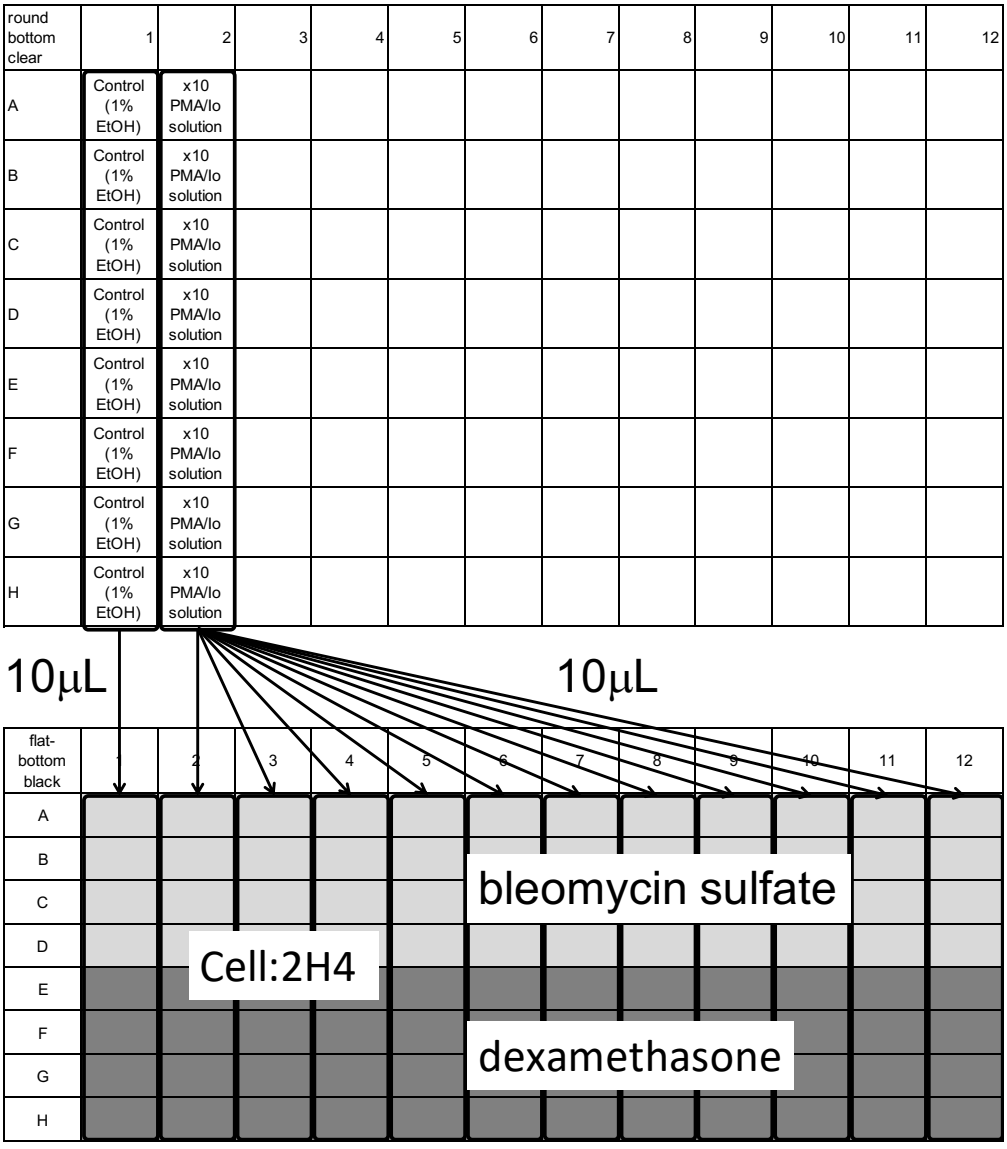
7-8 Addition of PMA/ionomycin to 2H4

Twenty-four hours after the addition of bleomycin sulfate and dexamethasone, add 10 μL of control or PMA/ionomycin solution prepared in §6-3 to the cells (#A1-#H1 or #A2-#H12, respectively) using an 8 channel or 12 channel pipetman after pipetting 20 times. Make sure that the apex of the tip is dipped into the medium. Change tips every line you add. Seal the plate, shake the plate with a plateshaker and incubate in a CO_2 incubator for 6 hours (37°C, CO_2, 5%). (cf. Figure 25)

Figure 25



8. Calculation of the transmittance factors

Color discrimination in multi-color reporter assays is generally achieved using detectors (luminometer and plate reader) equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmittance factors of these filters for each bio-luminescence signal color must be calibrated prior to all experiments by following the protocols below.

8-1 Reagents

- Single reference samples:

Lyophilized luciferase enzyme reagent for stable luciferase green (SLG)
Lyophilized luciferase enzyme reagent for stable luciferase orange (SLO)
Lyophilized luciferase enzyme reagent for stable luciferase red (SLR)

- Assay reagent:

Tripluc® Luciferase assay reagent（TOYOBO Cat#MRA-301）

- B medium: for luciferase assay (30 mL, stored at 2- 8°C)

Reagent	Company	Conc.	Final conc. in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1A Lot: 1524129	-	10 %	3 mL

8-2 Preparation of luminescence reaction solution

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature either in a water bath or at ambient air temperature. Power on the luminometer 30 min before starting the measurement to allow the photomultiplier to stabilize.

Add 200 μL of 100 mM Tris-HCl (pH8.0) contains 10 % glycerol to each tube of lyophilized reference sample to dissolve the enzymes, divide into 10 μL aliquots in 1.5 mL disposable tubes and store in a freezer at -80°C. The stored frozen solution of the reference samples can be used for up to 6 months.

Add 1 mL of the B medium to each tube of frozen reference sample (10 μL sample per tube). Keep the reference samples on ice to prevent deactivation.

8-3 Bioluminescence measurement

Transfer 100 µL of the diluted reference samples to a black 96 well plate (flat bottom) as shown below.

Figure 26

flat-bottom black	1	2	3	4	5	6	7	8	9	10	11	12

Transfer 100 µL of pre-warmed Tripluc to each well of the plate containing the reference sample using a pipetman. Shake the plate for 10 min at room temperature (about 25°C) using a plate shaker. Remove bubbles in the solutions in wells if they appear. Place the plate in the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1, F2) of the optical filters. An example of the raw output data is shown below.

Six transmittance factors of the optical filters were calculated as follow:

$$\text{Transmittance factor } (\kappa G_{R56}) = \frac{\#B1 \text{ of } F1 + \#B2 \text{ of } F1 + \#B3 \text{ of } F1}{\#B1 \text{ of } F0 + \#B2 \text{ of } F0 + \#B3 \text{ of } F0}$$

$$\text{Transmittance factor } (\kappa O_{R56}) = \frac{\#D1 \text{ of } F1 + \#D2 \text{ of } F1 + \#D3 \text{ of } F1}{\#D1 \text{ of } F0 + \#D2 \text{ of } F0 + \#D3 \text{ of } F0}$$

$$\text{Transmittance factor } (\kappa R_{R56}) = \frac{\#F1 \text{ of } F1 + \#F2 \text{ of } F1 + \#F3 \text{ of } F1}{\#F1 \text{ of } F0 + \#F2 \text{ of } F0 + \#F3 \text{ of } F0}$$

$$\text{Transmittance factor } (\kappa G_{R60}) = \frac{\#B1 \text{ of } F2 + \#B2 \text{ of } F2 + \#B3 \text{ of } F2}{\#B1 \text{ of } F0 + \#B2 \text{ of } F0 + \#B3 \text{ of } F0}$$

$$\text{Transmittance factor } (\kappa O_{R60}) = \frac{\#D1 \text{ of } F2 + \#D2 \text{ of } F2 + \#D3 \text{ of } F2}{\#D1 \text{ of } F0 + \#D2 \text{ of } F0 + \#D3 \text{ of } F0}$$

$$\text{Transmittance factor } (\kappa R_{R60}) = \frac{\#F1 \text{ of } F2 + \#F2 \text{ of } F2 + \#F3 \text{ of } F2}{\#F1 \text{ of } F0 + \#F2 \text{ of } F0 + \#F3 \text{ of } F0}$$

In the case shown above,

$$\text{Transmittance factors } (\kappa G_{R56}) = \frac{1269550 + 1257268 + 1289562}{3757015 + 3716611 + 3810382} = 0.338$$

Transmittance factors (κO_{R56})=$\frac{808550+813160+754174}{1202691+1210208+1122295}$=0.672

Transmittance factors (κR_{R56})=$\frac{2193723+1968240+1853873}{2465453+2207572+2077689}$=0.891

Transmittance factors (κG_{R60})= $\frac{236478+234079+240876}{3757015+3716611+3810382}$=0.06

Transmittance factors (κO_{R60})=$\frac{235121+235878+217432}{1202691+1210208+1122295}$=0.195

Transmittance factors (κR_{R60})=$\frac{1585258+1420099+1339265}{2465453+2207572+2077689}$=0.644

Calculated transmittance factors are used for all the measurements executed using the same luminometer.

Input the transmittance factors to #C6-#E7 of the “Data Input” sheet of the Data sheet as follow.

9. Measurement

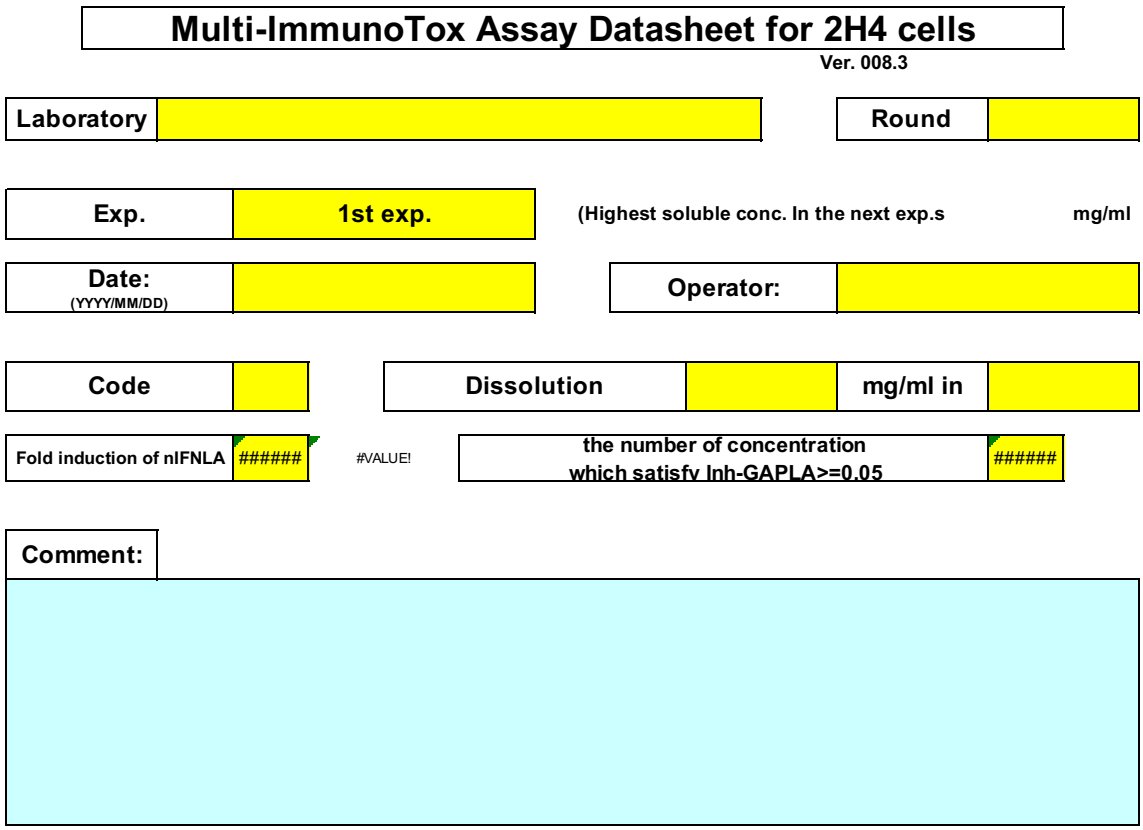
Please refer Appendix 1 for the principle of measurement of luciferase activity.

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature either in a water bath or at ambient air temperature. Power on the luminometer 30 min before starting the measurement to allow the photomultiplier to stabilize.

Transfer 100 μL of pre-warmed Tripluc from the reservoir to each well of the plate containing the reference sample using an 8 channel or 12 channel pipetman. Shake the plate for 10 min at room temperature (about 25°C) on a plate shaker. Remove bubbles in the solutions in the wells if they appear. Place the plate in the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence of (F0) and presence (F1, F2) of the optical filters.

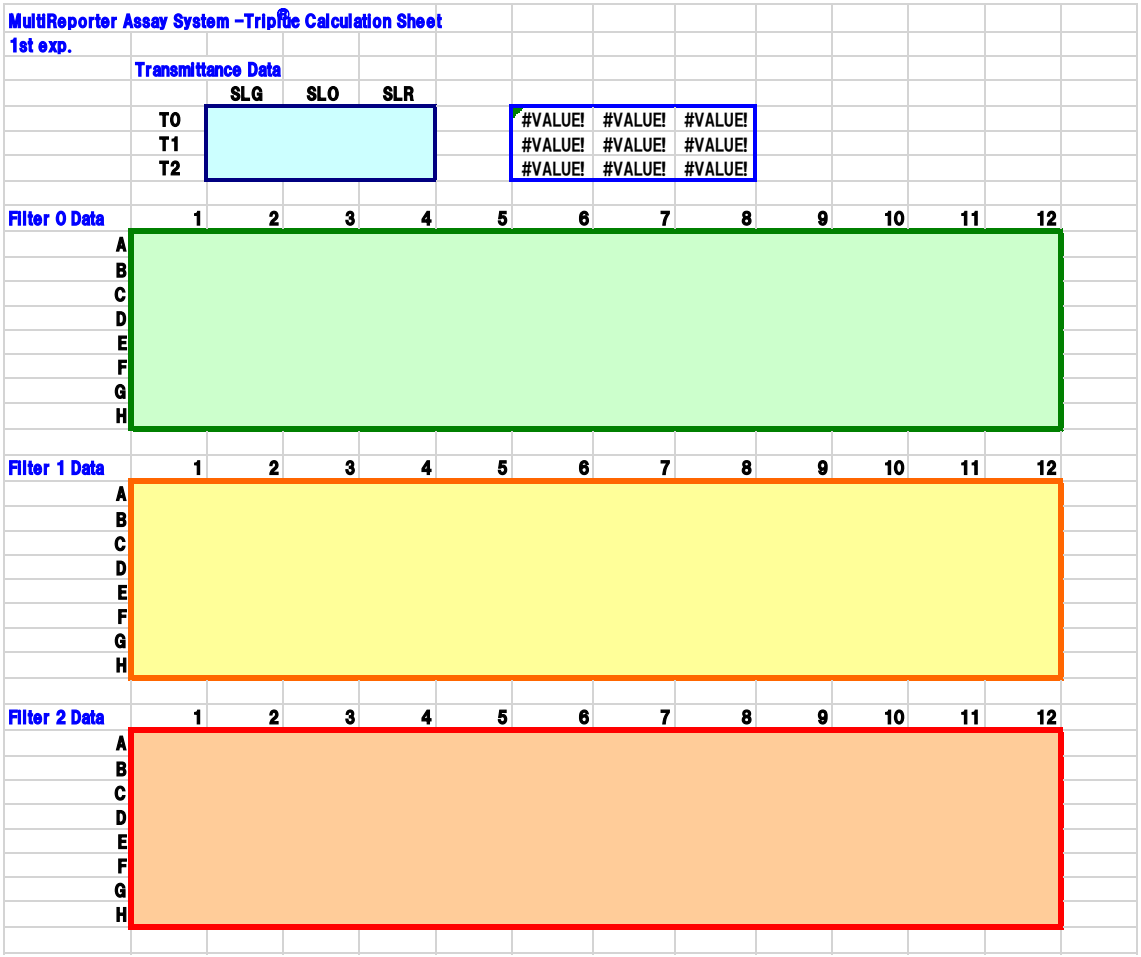
1st. Add the information regarding the name of laboratory, the round of experiments if multiple experimental sets are performed, the experiment number, date, the operator, chemical codes, dissolved in distilled water or DMSO, the prepared concentration, molecular weight of the chemicals and comments if any to Face Sheet of the data sheet.

Figure 29 “Face Sheet” of the data sheet



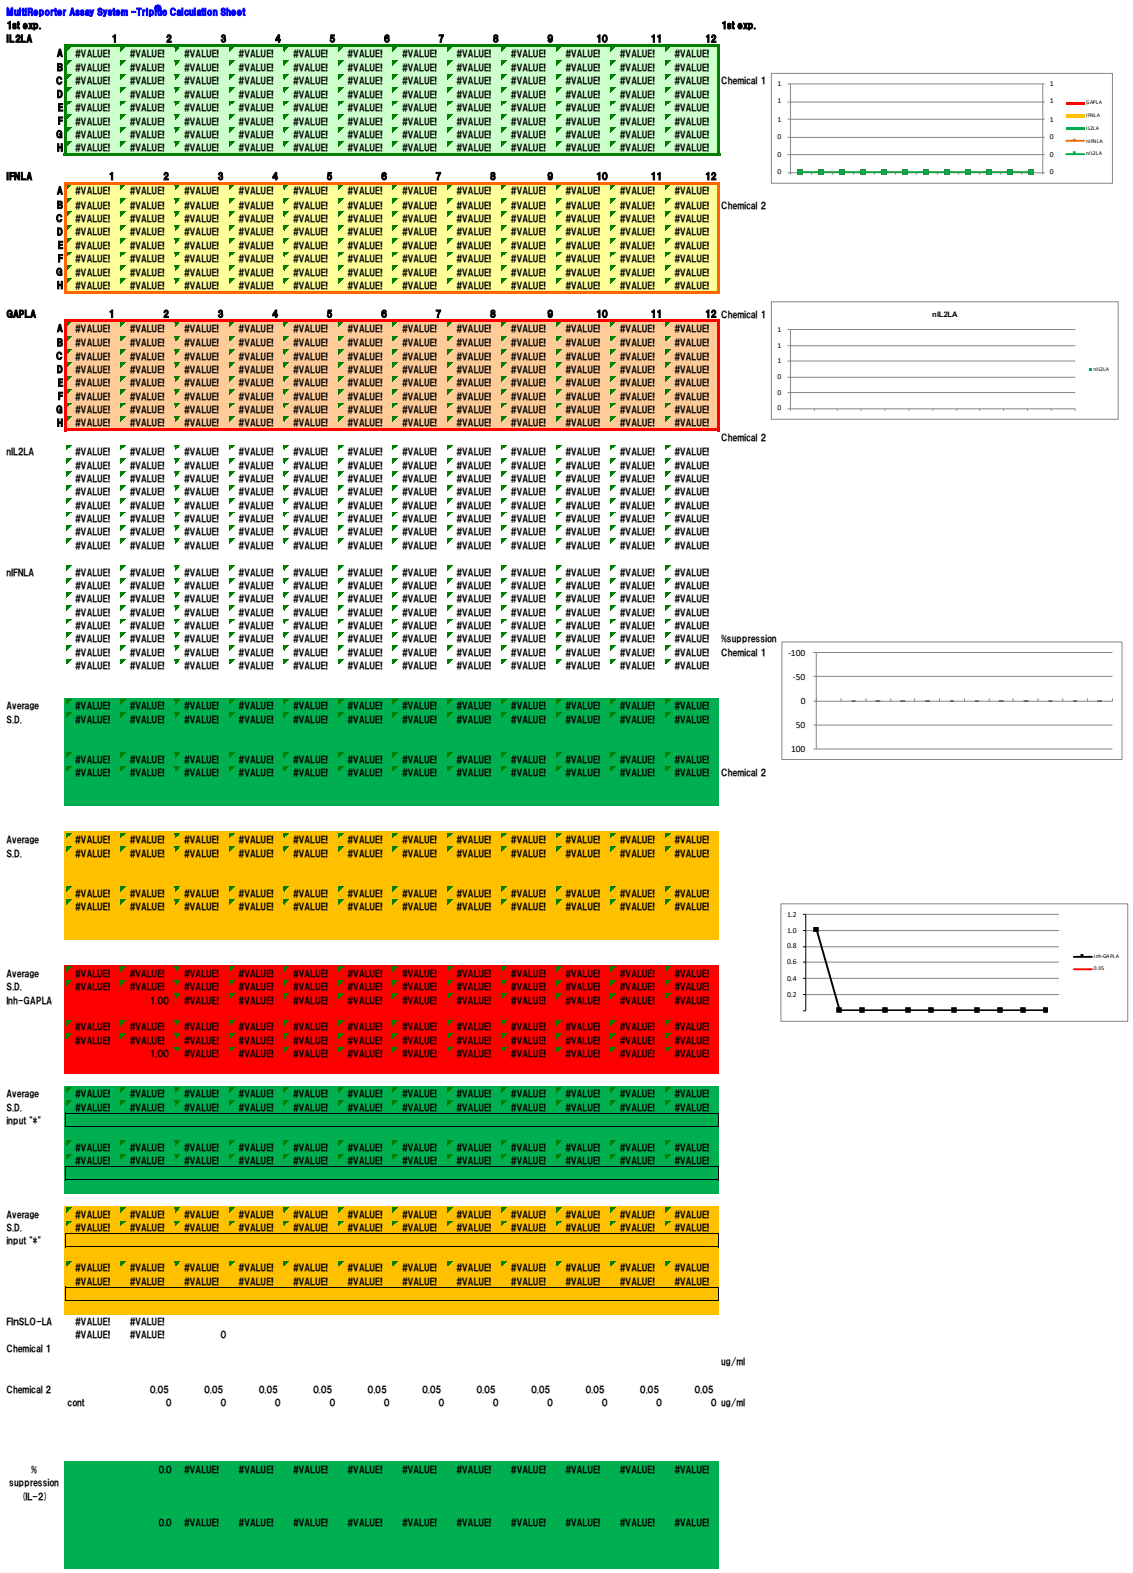
2nd. Copy the results of the F0, F1 and F2 measurements (values are expressed as counts) and paste them into the appropriate area in the “Data Input” sheet of the data sheet shown below. In addition, input the transmittance factors calculated in "§5. Calculation of the transmittance factors" to #C6-#E7 of the “Data Input” sheet.

Figure 30 “Data Input” sheet of the data sheet



Next, the calculated results for the parameters of the Multi-Immuno Tox assay for each concentration, e.g., IL2LA, IFNLA, GAPLA, nIL2LA, nIFNLA, the mean ± SD of IL2LA, the mean ± SD of IFNLA, the mean ± SD of GAPLA, % suppression and graphs will automatically appear on the “Result Format” sheet of the data sheet.

Figure 31 “Result Format” sheet of the data sheet



10. Data analysis

In the IL-2 Luc LTT, chemicals are first determined to be suppressive, stimulatory, or no effect based on the values of %suppression, which is defined as (nIL2LA of 2H4 cells treated with chemicals / nIL2LA of non-treated 2H4 cells) x 100. Then, considering the values of Inh-GAPLA, which is defined as GAPLA of 2H4 cells treated with chemicals / GAPLA of untreated cells, chemicals classified as suppressive, stimulatory, or no effect were further classified into leukocyte toxic, suppressive, stimulatory or no effect.

Definition of the parameters used in IL-2 Luc leukocyte toxicity test (IL-2 Luc LTT).

Abbreviations	Definition
GAPLA	SLR luciferase activity reflecting GAPDH promoter activity
IL2LA	SLG luciferase activity reflecting IL-2 promoter activity of 2H4 cells
IFNLA	SLO luciferase activity reflecting IFN-g promoter activity of 2H4 cells
nIL2LA	IL2LA/GAPLA of 2H4 cells
nIFNLA	IFNLA/GALA of 2H4 cells
% suppression	(nIL2LA of 2H4 cells treated with chemicals/ nIL2LA of non-treated 2H4 cells) x 100
CV05	The lowest concentration of the chemical at which Inh-GAPLA becomes < 0.05
Inh-GAPLA	GAPLA of 2H4 cells treated with chemicals /GAPLA of untreated cells
Min Inh-GAPLA	The minimum value of Inh-GAPLA of each experiment

11. Criteria

11-1 Acceptance criteria

The following acceptance criteria should be met when using the MITA method. In each time of the experiments, a control experiment examining nIFNLA of 2H4 cells treated with PMA/Io and nIFNLA of non-treated 2H4 cells must be conducted. Then, the fold induction of nIFNLA of 2H4 cells treated with PMA/Ionomycin to nIFNLA of non-treated 2H4 cells is calculated. If the fold induction is less than 3.0, the results obtained from these experiments should be rejected.

11-2 Criterion to determine leukocyte toxic or non-leukocyte toxic in the IL-2 Luc LTT

The experiments are repeated until 2 consistent leukocyte toxic results, indeterminate results, or non-leukocyte toxic results are obtained. When 2 consistent results are obtained, the chemicals are judged as indicated by the obtained consistent results.

In each experiment, if chemicals meet the following criteria described below and give Min Inh-GAPLA < 0.7, they are judged as leukocyte toxic. Otherwise, they are judged as provisional non-leukocyte toxic.

The criteria for stimulatory:

1./ The mean of % suppression is ≤-35 (stimulatory) with statistical significance. The statistical significance is judged by its 95% confidence interval.

2./ The result shows 2 or more consecutive statistically significant stimulatory data points or 1 statistically significant stimulatory data point with a trend in which at least 3 consecutive data points decrease in a dose-dependent manner. In the latter case, the trend can cross 0, as long as only 1 data point shows the opposite effect without statistical significance.

3./ The results are judged using only data obtained at the concentration at which Inh-GAPLA is ≥0.05.

Of chemicals that are not judged as provisional non-leukocyte toxic, if the chemicals that are insoluble at 10 mg/mL in distilled water do not give statistically significant suppressive or stimulatory data points and give Min Inh-GAPLA ≥ 0.7, they are judged as indeterminate because they may not be dissolved in the vehicle at the concentration sufficient to show the effects. Otherwise, they are judged as non-leukocyte toxic.

Appendix 1 Principle of measurement of luciferase activity

MultiReporter Assay System -Tripluc- can be used with a microplate-type luminometer with a multi-color detection system, which can equip two optical filters (e.g. Phelios AB-2350 (ATTO), ARVO (PerkinElmer), Tristar LB941 (Berthold)). The optical filters used in measurement are a 560 nm long-pass filter and a 600 nm long-pass filter.

(1) Measurement of three-color luciferase with two optical filters.

This is an example using Phelios AB-2350 (ATTO). This luminometer equips a 560 nm long-pass filter (560 nm LP, Filter 1) and a 600 nm long pass filter (600 nm LP, Filter 2) for optical isolation.

First, using luciferase enzyme reagent of SLG (λmax = 550 nm), SLO (λmax = 580 nm) and SLR (λmax = 630 nm), measure i) the intensity of light without filter (all optical), ii) the intensity of 560 nm LP (Filter 1) transmitted light iii) the intensity of 600 nm LP (Filter 2) transmitted light, and calculate the coefficient factor listed below.

Coefficient factor		Abbreviation	Definition
SLG	Filter 1 transmittance factor	κG_{R56}	The intensity of 560 nm LP (Filter 1) transmitted SLG / the intensity of SLG without filter (all optical)
	Filter 2 transmittance factor	κG_{R60}	The intensity of 600 nm LP (Filter 2) transmitted SLG / the intensity of SLG without filter (all optical)
SLO	Filter 1 transmittance factor	κO_{R56}	The intensity of 560 nm LP (Filter 1) transmitted SLO / the intensity of SLO without filter (all optical)
	Filter 2 transmittance factor	κO_{R60}	The intensity of 600 nm LP (Filter 2) transmitted SLO / the intensity of SLO without filter (all optical)
SLR	Filter 1 transmittance factor	κR_{R56}	The intensity of 560 nm LP (Filter 1) transmitted SLR / the

			intensity of SLR without filter (all optical)
	Filter 2 transmittance factor	κR_{R60}	The intensity of 600 nm LP (Filter 2) transmitted SLR / the intensity of SLR without filter (all optical)

When the intensity of SLG, SLO and SLR in test sample are defined as G, O and R, respectively, i) the intensity of light without filter (all optical): F0, ii) the intensity of 560 nm LP (Filter 1) transmitted light and iii) the intensity of 600 nm LP (Filter 2) transmitted light are described as below.

$F0=G+O+R$

$F1=\kappa G_{R56} \times G + \kappa O_{R56} \times O + \kappa R_{R56} \times R$

$F2=\kappa G_{R60} \times G + \kappa O_{R60} \times O + \kappa R_{R60} \times R$

These formulas can be rephrased as follows

$$\begin{pmatrix} F0 \\ F1 \\ F2 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \kappa G_{R56} & \kappa O_{R56} & \kappa R_{R56} \\ \kappa G_{R60} & \kappa O_{R60} & \kappa R_{R60} \end{pmatrix} \begin{pmatrix} G \\ O \\ R \end{pmatrix}$$

Then using calculated coefficient factors and measured F0, F1 and F2, you can calculate G, O and R-value as follows.

$$\begin{pmatrix} G \\ O \\ R \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \kappa G_{R56} & \kappa O_{R56} & \kappa R_{R56} \\ \kappa G_{R60} & \kappa O_{R60} & \kappa R_{R60} \end{pmatrix}^{-1} \begin{pmatrix} F0 \\ F1 \\ F2 \end{pmatrix}$$

This calculation can be performed using the functions "MININVERSE" and "MMULT" in Microsoft Excel. These calculations are integrated in the Data Sheet.

Appendix 2　Validation of reagents and equipment

5-1 Measurement of transmittance of optical filter for multicolor measurement

For color discriminations in the multi-color reporter assay, detectors (luminometer and plate reader) are usually equipped with optical filters, such as sharp-cut (long-pass) filters and band-pass filters. The transmittance factors of these filters for each bioluminescence signal color have to be calibrated prior to all experiments by following the protocols below.

5-1-1 Reagents

・Single reference samples:

Lyophilized luciferase enzyme reagent of SLG

Lyophilized luciferase enzyme reagent of SLO

Lyophilized luciferase enzyme reagent of SLR

・Assay reagent:

Tripluc® Luciferase assay reagent（TOYOBO Cat#MRA-301）

・B medium: for luciferase assay (30 mL, stored at 2 – 8°C)

Reagent	Company	Conc.	Final conc. in medium	Required amount
RPMI-1640	GIBCO #11875-093	-	-	27 mL
FBS	Biological Industries Cat#04-001-1A Lot: 1524129	-	10 %	3 mL

5-1-2 Calibration

5-1-2-1 Preparation of luminescence reaction solution

Thaw Tripluc® Luciferase assay reagent (Tripluc) and keep it at room temperature by bathing in water or ambient air. Start the luminometer 30 min before starting the measurement for stabilization of the photomultiplier.

Add 200 μL of 100 mM Tris-HCl (pH8.0) contains 10% glycerol to each tube of the lyophilized reference samples to dissolve the enzymes, followed by separating them into 1.5 mL disposable tubes at 10 μL each and storing in a freezer at -80°C. The stored frozen solution of the reference samples can be used for one half year.

Add 1 mL of the B medium to each tube of the frozen reference sample (10 μL in a tube) and label them as SLG1/1, SLO1/1 and SLR1/1. Keep the reference samples on ice to prevent deactivation.

Prepare dilution series of the single reference samples of SLG, SLO and SLR as follows. Dilute 0.3 mL of each 1/1 solution with 0.9 mL of the B medium to make SLG1/4, SLO1/4 and SLR1/4. In the same manner, prepare 1/16 and 1/64 solution of each. Keep diluted reference samples on ice.

5-1-2-2 Bioluminescence measurement

Transfer 100 µL of the diluted reference samples to a black 96 well plate (flat bottom) as shown below.

Transfer 100 µL of pre-warmed Tripluc to each well containing the reference samples of the plate using a pipetman. Shake the plate for 10 min at room temperature (about 25°C) with a plate shaker. Remove bubbles on the solutions in wells if they appear. Place the plate into the luminometer to measure the luciferase activity. Bioluminescence is measured for 3 sec each in the absence (F0) and presence (F1, F2) of the optical filters.

Copy the results of the F0, F1 and F2 measurement (values are expressed as counts) and paste it to the appropriate area in the “Data Input” sheet of the data sheet for data analyses shown below.

Record all the results for quality control.

5-2 Quality control of equipment

In order to confirm the detector stability as the quality control, the reference luciferase sample, optical property, the protocol described here should be performed at the beginning of the experiments every day.

5-2-1 Light source

LED Plate: Reference LED light source plates equipped with stabilized red, green, and blue LEDs are commercially available. For example,

TRIANT® (wSL-0001) by ATTO (Tokyo, Japan)

L12367 by Hamamatsu Photonics (Shizuoka, Japan)

5-2-2 Data collection (an example using TRIANT® by ATTO)

1) Start luminometer 30 min before starting the measurement for stabilization of the photomultiplier.
2) Start LED plate and select “PMT” mode.
3) Select three-color (BRG) mode and adjust light intensity to 1/10 (10E-1).

4) Place the LED plate into the luminometer. Light intensity is measured for 3 sec each in the absence (F0) and presence (F2) of the optical filter.
5) Blue, green, and red LEDs are located at the position of #F6, #E6, and #D6, respectively. Copy the collected data of each position to the appropriate area on Sheet "LED" in the excel file of the data sheet.
6) Check the photo-detector performance by comparing with old data of the LED plate. For quality control purpose, every collected data should be recorded.
7) LED plate data typically fluctuates up to 1.5% (σ). Disagreement to the old data should be less than 3×σ (= 4.5%).

PROJECT TITLE

The modification of the prediction model of the IL-8 Lu assay (OECD TG442E) to improve its performance

SUBMITTED BY (Country / European Commission / Secretariat)

Japan

DATE OF SUBMISSION TO THE SECRETARIAT

November 11th, 2020

DETAILS OF LEAD COUNTRY/CONSORTIUM

Country /Organisation:	Japan
Agency/ministry/Other:	National Institute of Health Sciences
Mail Address:	3-25-26 Tonomachi, Kawasaki-ku, Kawasaki 210-9501, Japan
Phone/fax:	+81-44-270-6597
Email:	h-kojima@nihs.go.jp

PROJECT OUTCOMES

☐ New Test Guideline	☐ Guidance document
☒ Revised Test Guideline	☐ Detailed Review Paper
☐ Deletion of an existing Test Guideline	☐ Other, please specify below

MAIN OBJECTIVE OF THE PROPOSAL (max. 150 words)

The proposed project aims to improve the performance of the IL8 Luc test method included in TG 442E by modifying the prediction model of the IL-8 Luc assay. The revised prediction model uses an indicator of cytotoxicity, based on glyceraldehyde 3-phosphate dehydrogenase luciferase activity (GAPLA). Based on this revised prediction model, inconclusive chemicals are judged negative if they show evidence of cytotoxicity. This modification reduces the number of inconclusive chemicals and increases the specificity of the assay.

PROPOSED WORK PLAN and RESOURCE NEEDS:

1. Draft workplan for development of the proposal, including any need to establish Ad Hoc Expert Group and mode of meetings (face-to-face, teleconference; electronic discussion group).

Indicate key milestones, including first and subsequent drafts of documents and timing of meetings.

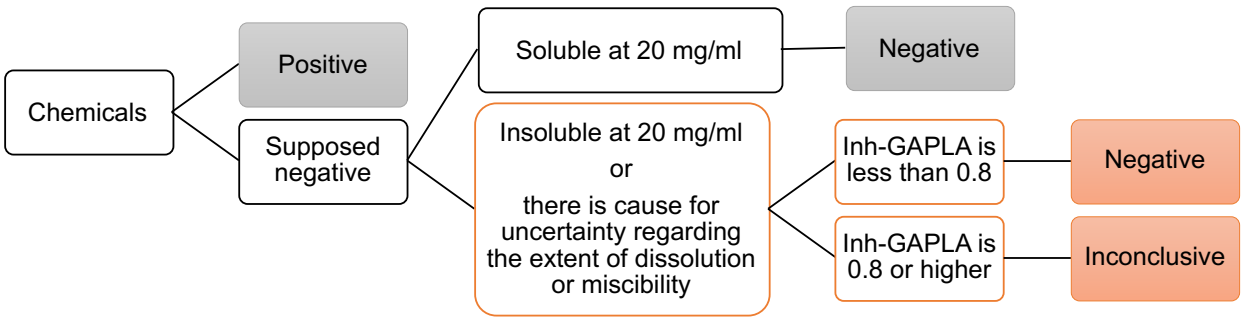
Tohoku University developed the IL-8 Luc assay as the *in vitro* test addressing the third key event of the skin sensitisation Adverse Outcome Pathway (AOP),. This assay detects the expression of IL-8 in the human monocytic leukaemia cell line THP-1. The IL-8 Luc assay has been adopted as Appendix III of Test Guideline (TG) 442E by the Organisation for Economic Co-operation and Development (OECD). According to TG 442E, the IL-8 Luc assay can be used for supporting the discrimination between skin sensitisers and non-sensitisers. In this project, it is proposed to modify the prediction model of the IL-8 Luc assay in order to improve the performance of the assay. The prediction model would focus on the evaluation cytotoxicity based on glyceraldehyde 3-phosphate dehydrogenase luciferase activity (GAPLA).

We propose to modify the prediction model. The modified part is written red.

Prediction model

32. Test chemicals that provide two positive results from among the 1st, 2nd, 3rd. and 4th runs are identified as positives whereas those that give three negative results from among the 1st, 2nd, 3rd and 4th runs are identified as supposed negative (Table 2). Among supposed negative chemicals, if chemicals are dissolved at 20 mg/ml in X-VOVO™ 15, they are judged as negative. If chemicals are not dissolved at 20 mg/ml in X-VOVO™ 15, or there is cause for uncertainty regarding the extent of dissolution or miscibility, chemicals that give Inh-less than 0.8 of GAPLA are judged as negative, while those that give 0.8 or higher of Inh-GAPLA should not be considered (Figure 1).

Figure 1. Prediction model for final judgment



This proposal with the revised text of TG 442E for the IL-8 Luc assay was already discussed at the tele-conference of OECD expert group for skin sensitisation (EG) on 30th October 2020. There was no particular comment on the proposed revisions which make the modified prediction model. If TG 442E can be revised upon approval of the SPSF by the Working Group of the National Coordinators of the Test Guidelines Programme (WNT) in 2021 and the revised TG442E will be submitted by Japan 2nd Q in 2021. This draft will be discussed by EG and WNT and Japan wishes to be accepted this revised TG 442E in 2022.

2. Will additional information, including generation or collection of data, be required? If yes, please describe the anticipated process and timelines.

Japan proposes additional information and requires no further data. False negative judgment due to poor chemical solubility is a problem with *in vitro* skin sensitisation tests. Water-insoluble chemicals are typically dissolved in DMSO in most sensitisation tests but precipitate when diluted with medium beyond their solubility in water. Such tests lack procedures to rule out false negative judgments due to poor solubility. The IL-8 Luc assay (OECD442E) is unique in that if chemicals do not dissolve at 20 mg/mL in medium and have no effect on IL-8 luciferase activity (IL8LA), they are excluded from judgment by classifying them as inconclusive. The purpose of the present study is to reduce the number of inconclusive chemicals and improve assay performance.

The IL-8 Luc assay can simultaneously examine glyceraldehyde 3-phosphate dehydrogenase (GAPDH) luciferase activity (GAPLA) and IL8LA. GAPDH mRNA is ubiquitously expressed at moderately abundant levels. It is frequently used as an endogenous control for quantitative real time polymerase chain reaction in some experimental systems, because its expression is constant at different times and after experimental manipulation (Edwards and Denhardt, 1985; Mori et al., 2008; Winer et al., 1999). Although there are several reports suggesting that its use as an internal standard is inappropriate in some cases (Oliveira et al., 1999; Thellin et al., 1999), in general within-tissue variation of GAPDH mRNA expression levels is small whereas between-tissue variation can be substantial, depending on tissue type (Barber et al., 2005). To improve the performance of the IL-8 Luc assay, we thought that GAPLA can be a marker of cytotoxicity of chemicals and thus it can be a marker indicating that chemicals are dissolved in medium because chemicals cannot induce cytotoxicity if they are not dissolved in medium. To demonstrate that GAPLA is a marker of cytotoxicity of chemicals, we examined the correlation between the reduction of GAPLA (defined as Inh-GAPLA) and the reduction of propidium iodide (PI)-excluding cells after chemical treatment for representative three sensitizers and three non-sensitizers.

Thus, THP-G8 cells were treated with various concentrations of the three sensitizers DNCB, 4-NBB and diethylmaleate, and the three non-sensitizers SLS, limonene and streptomycin sulfate. The cells were examined for Inh-GAPLA after 16 h of chemical treatment, and the number of PI-excluding cells was determined after 16 h, 24 h, and 48 h of chemical treatment. All the chemicals were dissolved and diluted according to the protocol for the IL-8 Luc assay, then THP-G8 cells were stimulated using the concentration of each chemical at which the values of Inh-GAPLA distributed from 0.02 to 1.0. These concentrations of chemicals were determined based on in-house data.

When these cells were cultured during 48 h, THP-G8 cells that gave less than 0.8 of Inh-GAPLA reduced PI excluding cells dose-dependently and chemicals providing an Inh-GAPLA value below 0.8 always reduced the ratio of PI-excluding cells to less than 0.6. On the other hand, the chemicals providing more than 0.8 of Inh-GAPLA maintained more than 0.8 of PI excluding cells (Fig. 1). Only THP-G8 cells treated with DNCB that gave 0.908 of Inf-GAPLA reduced PI reduction to 0.6 after 48 h of culture.

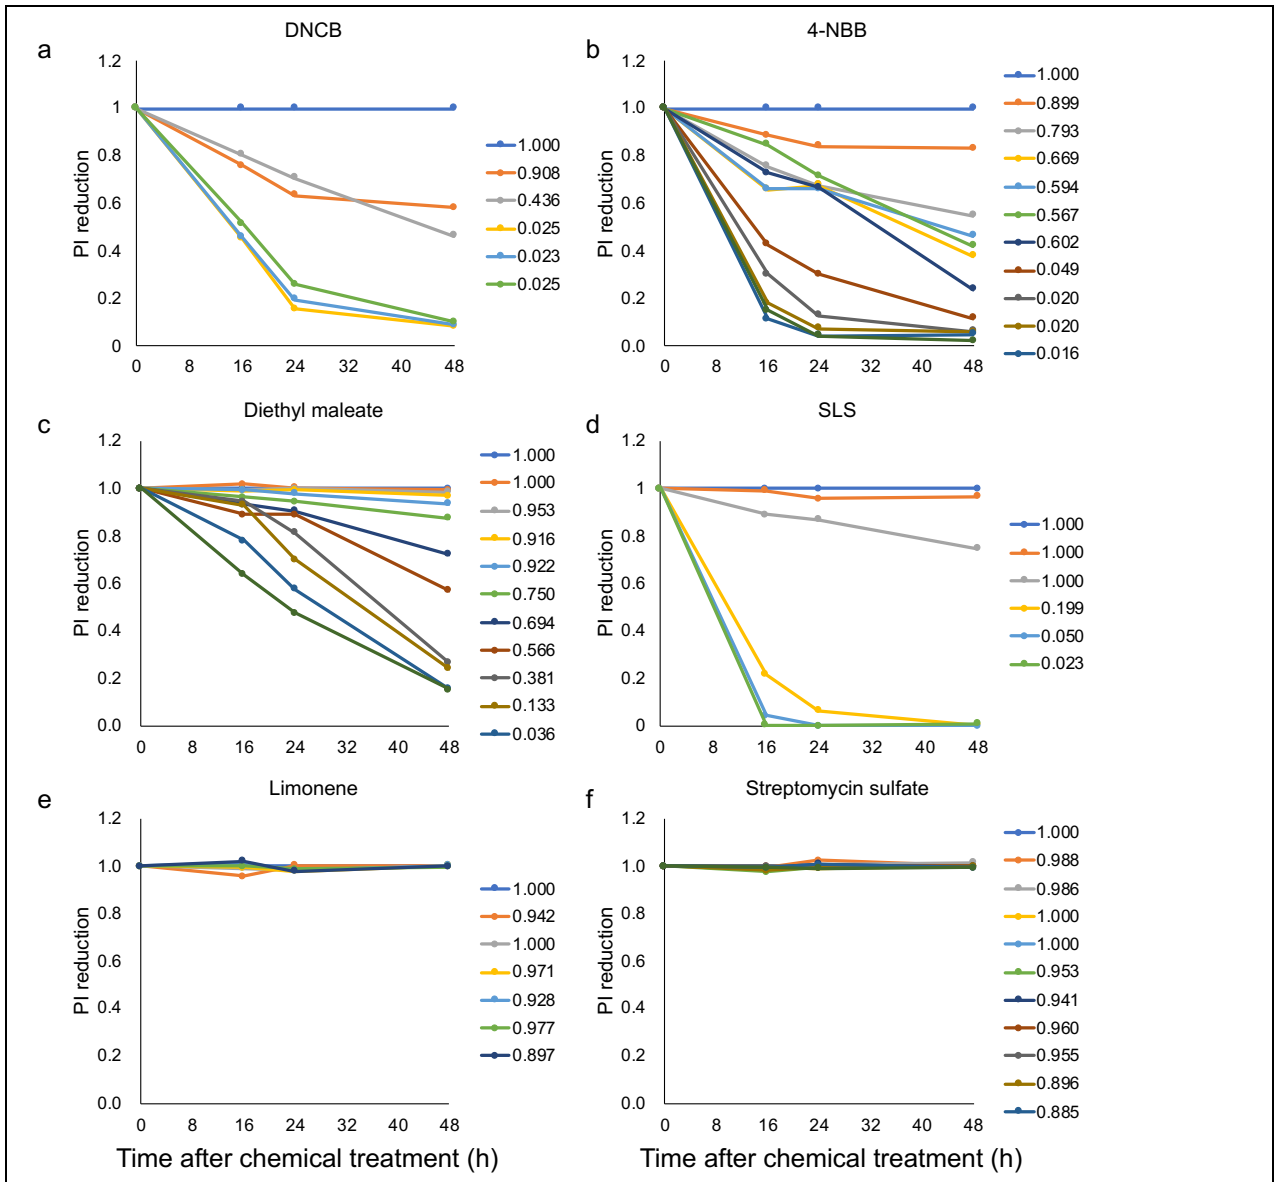


Fig. 1. PI reduction in THP-G8 cells treated with chemicals decreases as the level of Inh-GAPLA decreases and the culture period increases.
THP-G8 cells treated with various concentrations of the three sensitizers DNCB, 4-NBB and diethylmaleate, and the three non-sensitizers SLS, limonene and streptomycin sulfate, were examined for Inh-GAPLA after 16 h and for the number of PI-excluding cells after 16 h, 24 h, and 48 h of chemical treatment. THP-G8 cells were stimulated using concentrations of chemicals at which the values of Inh-GAPLA distributed from 0.02 to 1.0. The reduction in PI of THP-G8 cells treated with each concentration of chemical is shown at 0 h, 16 h, 24 h, and 48 h. Each line is labeled with an Inh-GAPLA value for THP-G8 cells treated with the concentration of chemical at which PI reduction was measured.

When Inh-GAPLA and PI reduction values for all chemicals were summarized and examined for correlation, these two parameters gave a significant correlation at 16 h, 24 h, and 48 h (Fig. 2). Furthermore, the correlation strengthened with increased culture period, with correlation coefficients after 16 h, 24 h, and 48 h of 0.775, 0.863, and 0.935, respectively (Kimura et al., 2020).

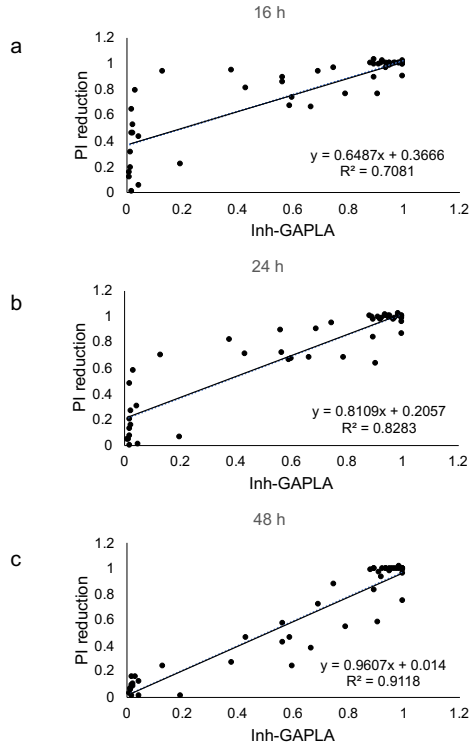

Fig. 2. There is a significant correlation between Inh-GAPLA and PI reduction values with strengthened correlation, depending on the culture period
Inh-GAPLA and PI reduction values for all chemicals were examined for correlation at three time points (16 h, 24 h, and 48 h) of chemical treatment.

These data suggest that Inh-GAPLA is a good marker for cell viability, with a strong correlation with PI-excluding cells, and that Inh-GAPLA below 0.8 indicates cytotoxicity of the test chemical, which in turn suggests that the chemical dissolved in X-VOVO^{TM} 15.

3. Indicate the estimated overall resource need (time/money) for member country / consortium and Secretariat

No financial resources were needed from any stakeholder.

Tohoku University in collaboration with the NIHS will provided the revised text in 2021. Co-operation of the OECD Secretariat is requested for distributing revised versions of the prediction model in TG 442E for the IL-8 Luc assay that need to be addressed. We do not foresee any additional resources that are needed beyond this.

4. Is this proposal intended to replace an existing Test Guideline or lead to the deletion of an existing Test Guideline?

Yes, the current prediction model in TG 442E for the IL-8 Luc assay would be revised, as described previously.

ESSENTIAL INFORMATION

In this section, please provide the information required by the Working Group of National Coordinators of the Test Guidelines Programme to assess the suitability of the project for the workplan of the Test Guidelines Programme

1. What is the existing or expected regulatory need/data requirement that will be met by the proposed outcome of the project? Please provide details below or as an attachment.

Of the 143 chemicals examined by the original IL-8 Luc assay (TG442E), 23 were classified as inconclusive. On the other hand, by applying the modified criteria, 10 of the 23 inconclusive chemicals were classified as non-sensitizers. Consequently, the performance of the modified IL-8 Luc assay was 93.9% for sensitivity, 68.0% for specificity, and 88.6% for accuracy, while that of the original IL-8 Luc assay was 95.8% for sensitivity, 53.0% for specificity, and 89.4% for accuracy. In addition, the number of chemicals classified as inconclusive is 13 by the modified IL-8 Luc assay and 23 by the original IL-8 Luc assay (Table 1). We also demonstrated LLNA potency category, solubility in 20 mg/ml of X-VIVO^{TM} 15, the average of maximum values of induction of IL8LA (Ind-IL8LA) and the average of minimum values of inhibition of GAPLA (Inh-GAPLA) in repeated experiments, the judgments by the original IL-8 Luc assay and by the modified IL-8 Luc assay, and LogK_{ow} of the 143 chemicals (the Supplementary Table 1 of the attached document 3). The terms of Ind-IL8LA and Inh-GAPLA were defined as follows.
Ind-IL8LA = IL8LA of THP-G8 cells treated with chemicals/IL8LA of untreated cells
Inh-GAPLA = GAPLA of THP G8 cells treated with chemicals/GAPLA of untreated cells.

Table 1. The comparison of the performance of the original IL-8 Luc assay and modified IL-8 Luc assay

	IL-8 Luc assay (OECD TG442E)	moIL-8 Luc assay
Total chemicals	143	143
Haptens	107	107
Non-haptens	36	36
Correct Positive	92	92
False Negative	4	6
Correct negative	9	17
False positive	8	8
Inconclusive	22	12
Out of applicability domain	8	8
Accuracy	89.3%	88.5%
Sensitivity	95.8%	93.8%
Specificity	52.9%	68.0%
Positive predictive value	91.9%	91.9%
Negaive predictive value	69.2%	73.9%

or as attachment No._3_

2. How will the work contribute to further international harmonisation of hazard and risk assessment? Please provide details below or as an attachment.

The non-animal skin sensitization tests like the IL-8 Luc assay is used in combination with other sources of information in the context of an IATA. OECD draft test guideline for defined approach is published and under public comments. Modifying the prediction model in this assay will contribute to OECD draft test guidelines for defined approach.

or as attachment No.__

3. How will the proposed project address issues and /or endpoints which are of major human health or environmental concerns? If there are existing Test Guidelines or projects in the work plan of the Test Guidelines Programme covering the same endpoint, please refer to these and describe the added value and usability of the proposed new test method. Please provide details below or as an attachment.

The proposal is to modify the prediction model in TG 442E for the IL-8 Luc assay. The IL-8 Luc assay is used in combination with other sources of information in the context of an IATA. Modifying the prediction model will contribute to attainment of better compatibility of animal welfare and prediction of chemical safety in the skin sensitization field.

or as attachment No.__

4. Will the project have general support from OECD member countries or is the outcome relevant for just one or a few member countries / stakeholders? Provide details of the countries and the rationale for this view below.

☒ Many countries ☐ A few countries ☐ Only for the submitting country

The outcome was generated by Tohoku University. The outcome is relevant to all OECD member countries.

5. If the Test Guideline is not intended for general use, indicate if the Test Guideline would be intended for:

☐ Specific (limited) applications such as pesticide usage, or

☐ for specific classes of chemicals (e.g. surfactants) rather than for chemicals in general.

6. If the expected outcome of this proposal is a Test Guideline or a Guidance Document, provide information on the intended use, applicability and limitations of the test method.

Due to the proposed revision, the modified IL-8 Luc assay aims to improve its performance and expand the applicability domain. It is useful revision for end users.

7. Provide supporting information on the validation status (i.e. relevance and reliability) of the method. Principles for validation of test methods for OECD Test Guidelines are described in Guidance Document 34.

Provide justification and rationale for the test, including data.

If there are no or limited data available to support the reliability and relevance of the proposed test, indicate if validation work is included in the project.

If there is no need for validation, provide a detailed justification.

TG 442E for the IL-8 Luc assay has already been adopted. The proposed modified IL-8 Luc assay slightly differs from the earlier version of TG 442E described previously. However, it is foreseen that further validation is not required because the modified points are minor and supported by experimental work (manuscript submitted).

8. Describe if the test method includes components, equipment or other scientific procedures that are covered (or pending) by Intellectual Property Rights (IPR) (e.g., patents, patent applications, industrial designs and trademarks). Information should be provided on the overall availability of the IPR-protected components including whether they are commercially available or require a Material Transfer Agreement (MTA) or other licensing agreements. In addition, a description of the IPR-covered component/test system should be disclosed. Note that the OECD has developed Guiding Principles on good practices for the availability/distribution of protected elements in OECD Test Guidelines. The test method developer will be requested to fill in and sign the FRAND Terms Licensing Declaration Form annexed to the Guiding Principles.

8.1 Nature of protected elements (e.g. reagent identity, cell line identity, specific process, etc.):

None

8.2 Form of protection (e.g. trademark, patent, etc.):

None

8.3 For users to access protected elements, please tick the relevant box(es):

☐ MTA required ☐ License requirement ☒ No agreement required

If a license or other agreement is foreseen, please note that terms and conditions should comply with FRAND and a signed declaration needs to be submitted if the project gets onto the work plan. See Annex 2 of the OECD Guiding Principles on Good Licensing Practices for Protected Elements in OECD TGs (2019).

8.4 Are you providing the agreement document(s) referred to in 8.3 with the SPSF:

☐ Yes ☒ No If no, what's the reason?

Not applicable.

8.5 How and where can users get access to protected elements?

The Standard Operating Procedure (SOP) for the IL-8 Luc assay and THP-G8 cells become available when this assay is accepted as the OECD TG. Laboratories that want to perform the test would obtain the THP-G8 cell line from GPC Lab. Co. Ltd., Tottori, Japan, upon signing a Material Transfer Agreement (MTA) in line with the conditions of the OECD template. THP-G8 cells will be maintained and quality-checked at regular intervals in GPC.

8.6 Has any search for existing patent(s) possibly associated with this test method been performed (e.g. through patent search or Freedom-To-Operate search). If yes, what was the outcome?

Not applicable

8.7 Does the test method include any Confidential Business Information? ☐ Yes ☒ No ☐ N/A

If yes, which ones?

<u>IMPORTANT NOTE:</u> Should the OECD and Expert Group working on the Test Guideline development discover that the information provided under Item 3 on IP elements be erroneous or be evolving in the course of the project, the project itself might be re-considered, suspended or cancelled.

9 Have Performance Standards been developed? ☐ Yes ☐ No ☒ N/A

ADDITIONAL INFORMATION

In this section please provide further information to allow the Working Group of National Coordinators of the Test Guidelines Programme to assess the suitability of the project for the workplan of the Test Guidelines Programme

1. If the expected outcome of the project proposal is a Test Guideline and is based on existing, regional or international documents such as guidelines, protocols or guidance material, please provide that information here or as an attachment.

It is expected that the reliability and usability of the modified TG 442E for the IL-8 Luc assay have been already verified because the revised part is only minor point for the prediction model from the earlier version of TG 442E, as described previously.

or as attachment No.__

2. If Animal Welfare considerations are addressed in the project proposal, provide details below or as an attachment. Explain if the project is aimed at refining, reducing and/or replacing the use of animals.

If the project is not specifically developed for animal welfare purposes, indicate if the animal welfare considerations have been a component of the project proposal.

Indicate if animal welfare considerations are irrelevant to the project, for example for physico-chemical properties.

The OECD has already adopted the TG 442E for the IL-8 Luc assay. Modifying the prediction model would improve the performance of this assay by reducing the number of inconclusive chemicals and increasing their specificity.

or as attachment No.__

3. Provide information on expected or possible resource savings in member countries as a result of this project.

As mentioned in additional information 2, modifying the prediction model would lead to a decrease in the use of animals for identifying skin sensitization potential. Generally, in vitro does not take times comparing with in vivo sensitization tests. We believe these mean resource savings in member countries.

4. If the expected outcome of the proposed project is a Guidance Document or Detailed Review Paper, will it be directly linked to the development of a particular Test Guideline or a series of Test Guidelines?

☐ Yes, it is the initial step in the development of a new or revision of existing Guidelines.

☐ Yes, additional guidance is needed for the most appropriate selection of the Guidelines on the subject.

☐ No, the guidance is on issues related to testing or the development of Test Guidelines in general.

There are __2_ attachments added to this form.

【試験方法】

1. HACベクターへのGAPDHSLR:IL8SLO(GAPDHR-IL8O) 遺伝子搭載

1-1 HACベクター保持CHO細胞を培養する。
1-2 プラスミド(CMV-LoxP:GAPDHR:IL8O:をHACベクターに搭載する。
1-3 G418で薬剤選抜を行い、耐性クローンを獲得する。
1-4 耐性クローンは、PCRにより染色体上へのGAPDHR-IL8O遺伝子移入を確認する。

2. GAPDHR-IL8O遺伝子搭載HACベクター保持細胞の機能評価

2-1 取得したGAPDHR-IL8O保持細胞候補クローンについて、TNFα及びIL-1応答性評価および核型解析を実施する。
2-2 TNFαまたはIL1 を添加した培地で2日間の培養を行い、発光量の変動をクロノスHT(ATTO)を用いて測定する。
2-3 各クローンの核型標本を作製し、HACベクターを保持していることを確認する。
2-4 TNF-αおよびIL-1応答性が良く、HACベクターが独立して保持されていることが確認されるクローンを選択する。

3. GAPDR-IL8O遺子搭伝載HACベクタ-のTHP-1細胞への移入

3-1 選択した細胞が十分に増えたタイミングでコルセミド添加培地に置換し、微小核を形成させる。
3-2 微小核を形成した細胞をサイトカラシン含有培地で満たし、遠心(8000rpm, 60min, 34℃)して、微小核を回収する。
3-3 ポリエチレングリコール(PEG)を用いて、THP1-IDAC細胞と微小核を融合し、HACベクターを移入する。
3-4 Blasticidin S で薬剤選抜を行い、耐性クローンを獲得する。
3-5 耐性クローンは、PCRにより染色体移入を確認する。

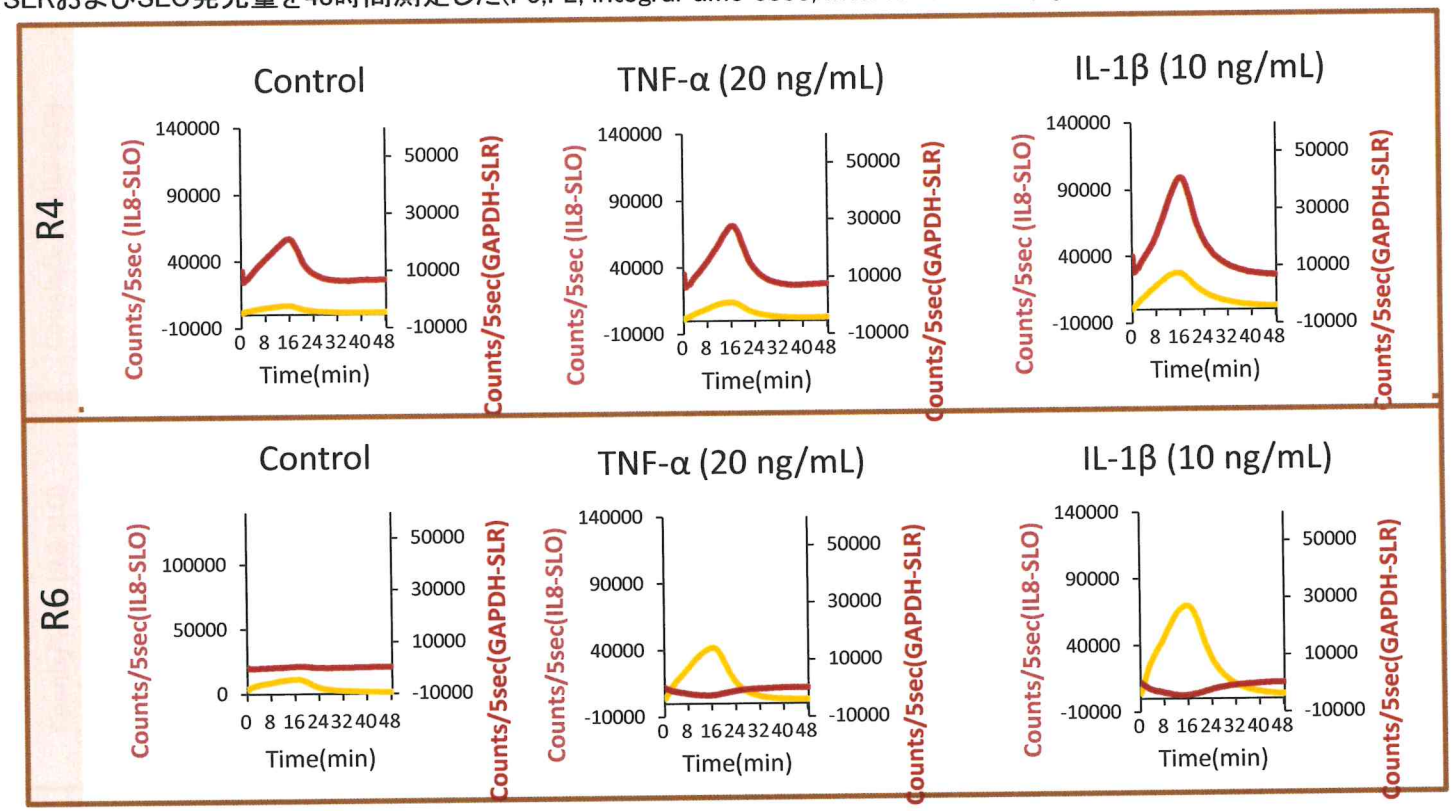
【2：GAPDHR-IL8O遺伝子搭載HACベクター保持細胞の機能評価TNFα・IL1応答性評価試験】

・PCRにて目的遺伝子の導入が確認でき、事前に実施したLucアッセイで高い蛍光値を示したHACベクター導入CHO細胞クローンについて下記条件で96well プレートに播種し、培地にTNFαおよびIL-1添加した際の発光量の変化を測定した。薬剤反応性と蛍光値および核型解析結果を考慮し、THP-1への微小核細胞誘導試験に用いるクローン（W3）を選択した。

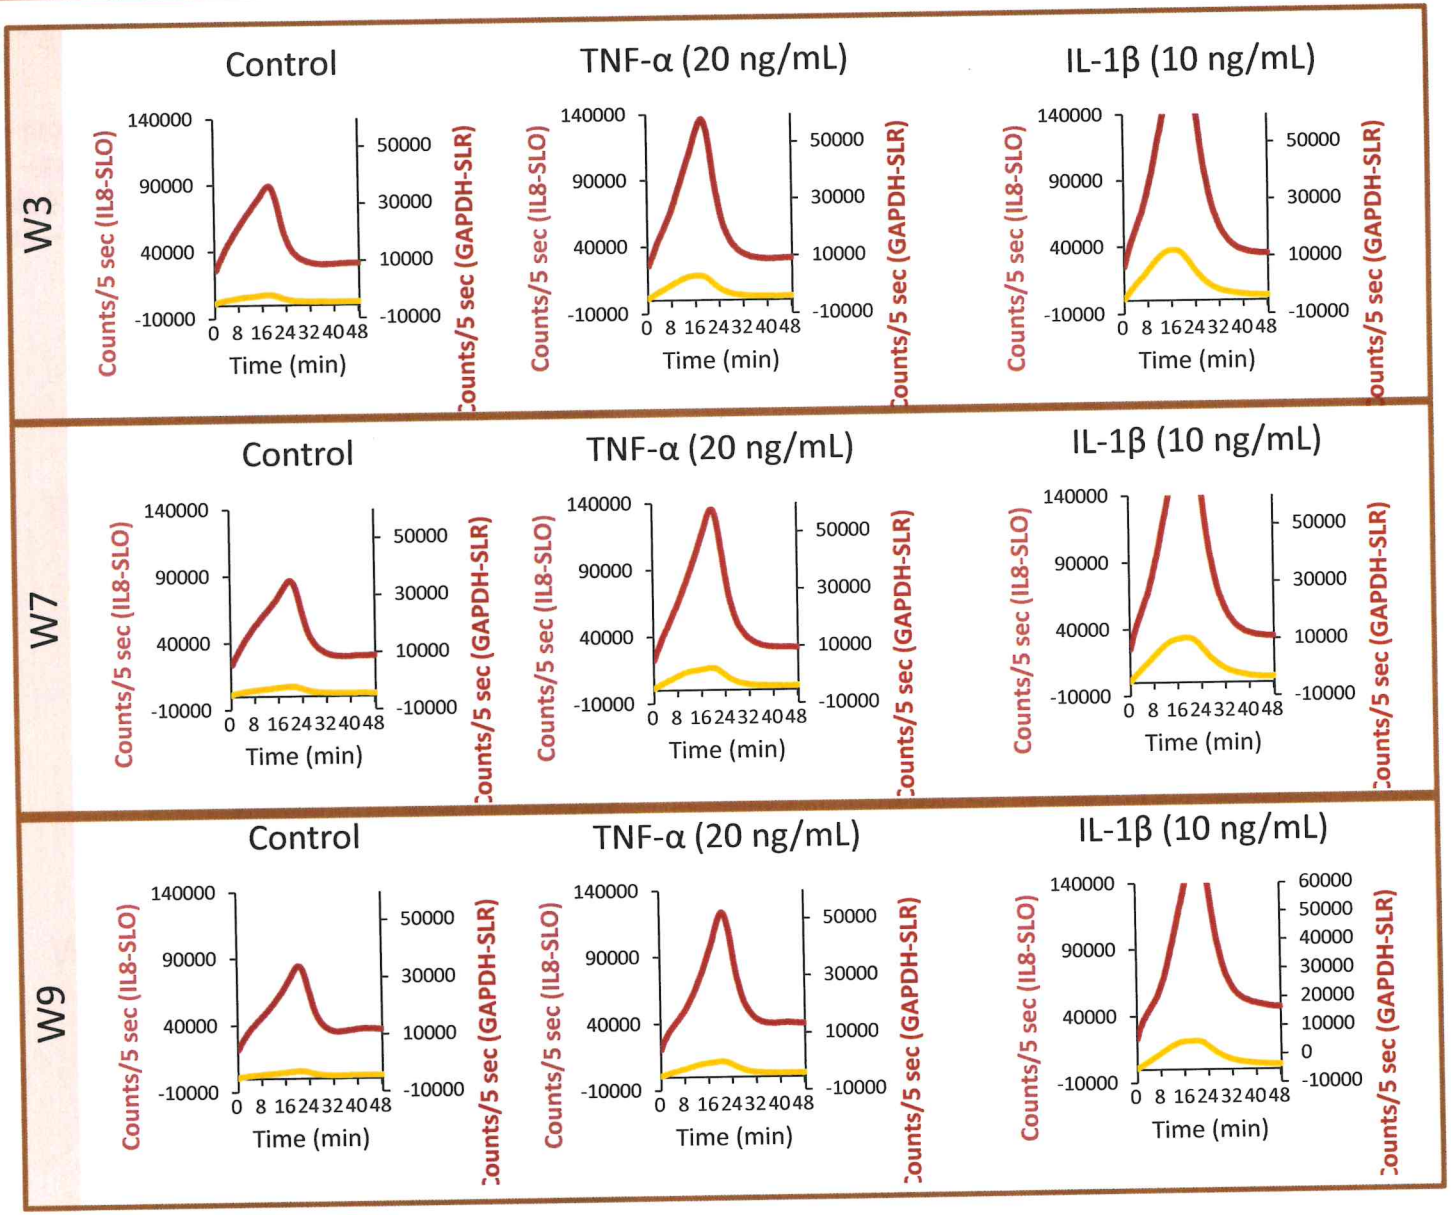
TNF-α・IL-1β応答性評価

試験条件

・5X103cells/wellで播種し、48時間後に各薬剤（TNF-α：20 ng/mL, IL-1β：:: 100 μM10ng/mL, D-luciferin）を添加した培地に交換した。
・Kronos HTにてSLRおよびSLO発光量を48時間測定した(F0,F2, integral time 5sec, interval time min) 。



GPC laboratory
Genome Program and Control



SLR・SLOの値が高W3, W7,W9を候補クローンとした。

核型解析

・HACベクター保持CHO細胞 5クローン（R4, R6, W3, W7, W9)について、核型標本（DAPI染色）を作製し、宿主染色体本数及びHACベクター保持率を調べた。
・遺伝子が搭載されたHACベクターを確実にTHP細胞に移入するため、HACベクターが1個保持されているものとしてW3およびW9を候補クローンとして選択した。

総括

CHO細胞内においてHACベクターにGAPDHSLR:IL8SLO遺伝子を搭載することができた。さらにこのHACベクターを微小核細胞融合法によりTHP-1 IDAC細胞に移入させることに成功した。

今後は、クローニング作業を実施し、導入遺伝子の動作確認（TNF α・IL1応答性評価試験）、THP-1IDAC細胞内におけるHACの保持状態確認（核型解析・FISH解析）及び遺伝子保持確認（PCR解析）へと順次検証を進めていくこととなる。
